One of the Toronto men speaking about the matter this morning said his principals had announced no change in their selling prices, and if any were to be made at the first of the year the chances were that he would be advised of it by now, or have some tip that it was coming, although the policy of some houses is to send out their changes immediately. Some of them believe that prices of tools that are made up and in stock are such that they cannot cut them much, and that if there is to be a new price they will have to secure labor and material at a lower price.

The prospects of a better supply of power in this district will be reflected in the sale of motors very shortly. There is undoubtedly a marked preference on the part of many manufacturers for motor drive for group or individual machines, but it has not been possible to secure power enough, so the sale of motors of the voltage sent on the Hydro line has been much curtailed.

In the Steel Market

Few changes are announced in the steel market this week. There seems to be some little doubt as to what extent the new prices apply to Canadian trade. The Carnegie mills, for instance, announce that in their products, such as structurals, bar mill material, plates, etc., they will now regard Canadian business as domestic. This ruling applied from the first day of December, and all orders that were on the books before that time are not put down at the new price. This ruling is satisfactory to the trade, as it had been expected that the old price would stand where a definite figure had been named on a contract.

The American Sheet and Tin Plate books have been opened for business in the States, but so far their Canadian office is not taking on business, although it is expected that this will be the case here in a few days. Neither is there any official confirmation of the rumor that they had decided to regard Canadian business as domestic trade, although on the other hand it would cause no surprise were this to be confirmed.

Some of the warehouses are not ready to take on all the shipments that are being made in their direction. One of the dealers stated his case as follows: We have been month after month waiting for delivery of our orders, particularly in sheets. Much of this was seasonable business, and now that stuff is coming through faster and the demand is lower, there is a danger of them swamping us with material. This does not mean that we are going to cancel, for we want to place the material in stock, but it does mean that we are not going to allow the mills to take advantage of the situation now that deliveries are more in their favor. As long as they spread their deliveries over a period, well and good, but there is not going to be any smothering done if we can prevent it."

The Matter of Prices

Prices remain much the same in the local market. Galvanized sheets are not by any means plentiful, the mills

POINTS IN WEEK'S MARKETING NOTES

Large buyers have advised the machine tool trade that there will be no buying until the first of the year.

—

New York reports indicate that makers of machine tools are in no hurry to announce any reduction in price, believing that such a step would not bring any new business into the market.

—

Some of the American sheet mills are opening their books for new business now, but the Canadian sales office of the Corporation has not yet taken on any new business.

—

There is a rumor on the street to the effect that the price of sheets in Canada from American mills will be the same as the price at which they are sold in the United States, but there is no official confirmation of this report as yet.

—

The United States Steel Products announce that Canadian business will now be regarded as domestic by their mills. This comes back to the same position that they occupied some months ago, before the increase was put on Canadian orders.

—

The average independent steel mill in United States is not operating at much over 50 per cent. of its capacity at the present time, while the Corporation is running at 85 to 90 per cent.

—

Makers of pig iron have very little business on hand, and a number of the furnaces in the United States have blown out during the past week.

—

On account of the high exchange rate, many buyers who have shipments coming in from the United States are asking for as much time as possible in the hope that the exchange may be a little more favorable to them.

—

With the prospect of securing more power, dealers are looking forward to an improvement in the sale of motors, both for group and individual drives.

having been turning out only a limited tonnage.

Black sheets are not a plentiful article, and this condition is not likely to improve, as the mills are not turning out many of these. The independents are largely down to a low rolling rate per day. They have very little business on their books and are reducing staffs in keeping with the amount of business that is offering. In some lines the advantage still rests with the independents, because they are in a position to give almost immediate shipment out of stock, whereas there are many lines on which it is still impossible to book business with the Corporation.

Tubes are in good demand now, and a brisk business is being done. Of course there is nothing unusual in this, as it has been the aame year after year. As soon as a ship ties up for the season work is started on repairing, and for the next two months the tube business ought to be a pretty fair trade.

Bar iron is seliing well, but perhaps the most active line in this section is band iron, the stovemakers having requirements in this line at present.

The Matter of Exchange

Now that the exchange on Canadian funds in New York has gone up over the 15 per cent. mark, there is a tendency on the part of many buyers to urge as long consideration as possible, in order that they may have a chance to get something better a little later on. Some of them have recently been fooled on this, because exchange, instead of crawling down has shown a marked tendency in the other direction. Some of the firms selling steel in Canada give fairly long terms of payment, and at any time in that period the buyer can take advantage of any drop in the exchange rate and make his payment against the account. Especially now with the rate high again, buyers are watching every day to see if there is any advantage in their favor in the changing quotations.

THE PREMIUM MARKET DID NOT DIE— IT SIMPLY WENT AND FADED AWAY

Special to CANADIAN MACHINERY.

PITTSBURGH, December 9.—Two more important steel mill products, wire and sheets, have come down to the Steel Corporation or Industrial Board level, and only one large line, tubular goods, remains. The readjustment in pipe may not come for quite a while, for pipe continues in excellent demand, with heavy requirements against contracts and some new buying of no small consequence in the open market. Pipe stands quite alone among finished steel products.

In the wire product readjustment one large independent interest took the lead, reducing its prices to 3.25c for plain wire and $3.25 for nails, these being the Steel Corporation prices. The $3.25 on nails is an Industrial Board price. The 3.25c on plain wire is an advanced price, the Industrial Board price having been 3.00c, the American Steel & Wire Company having advanced its price on wire last August by $5, leaving nails unchanged. While it may seem strange to have wire and nails on the same price basis, the differential has never reflected the actual cost of manufacture. For many years it was 10 cents, and for a short period long ago it was only five cents. The 25-cent spread in the Industrial Board schedule was a relic of the war time control.

The other independent wire interests showed no alacrity in following the lead of the first independent. This indifference is to be attributed to the fact that there is scarcely any demand in the open market, hence little temptation to engage in competition, while perhaps it was thought that some of the contract tonnage remaining on books could be saved. One independent, for instance, offered to adjust 4.25c nail contracts to 4.00c. Another reduced its nail price from 4.25c to 3.75c instead of to 3.25c, although it did make the full reduction, to 3.25c, on plain wire.

The Decline in Sheets

At the time of last report the sheet market, on a really desirable order, was practically down to a level just $10 a ton or a half cent a pound above the Steel Corporation prices, although no mill was openly quoting altogether as low. For a few days the position of several mills was that while they were quoting $10 a ton above the corporation prices they were willing to do the corporation prices if they were offered a good sized order, say 1,000 or 2,000 tons. The difficulty was that no such business appeared in the market. At this writing it is clear that at least one mill would quote the Steel Corporation prices even on an ordinary order, not waiting for an impossibly large order. Hence the independent sheet market is now quotable at the Steel Corporation level.

Late last week the American Sheet & Tin Plate Company opened its order books for the new sales period, nominally the second half of the year in the case of regular manufacturing consumers, but practically for the second quarter, since about three months of work has to be carried over from this year's contracts, the holdover being due to the company not having been able to operate at capacity on account of steel and fuel shortage and car shortage, at various times over the past six months and more.

The prices are of course as formerly: Tin plate, $77 per base box for 100-lb; blue annealed sheets, 10 gauge, 3.55c; black sheets, 28 gauge, 4.35c; galvanized sheets, 28 gauge, 5.70c.

End of Independent Market

The famous and spectacular independent market for steel products has thus come to a mute and inglorious end, excepting in the case of pipe. No one, perhaps could have imagined the independent market giving out so quietly. It can hardly be said to have done so active and energetic a thing as to die. It simply faded away. There was no important business offered as an incentive. The independent mills that reduced their prices first did not get any business to speak of by the operation, nor has buying been stimulated to any appreciable extent. Such wants as the country has seem to be supplied almost wholly by the Steel Corporation which so far as can be ascertained is operating as well as at any time, say at between 85 and 90 per cent. It must be that a large number of buyers have been on the corporation books, making purchases from independents simply as the corporation's allotments to them were insufficient. With respect to much of the country's business, then, the independents were simply getting the overflow.

Independent Operations

The different independents are operating at various rates, and there is also much starting and stopping from week to week, so that a close estimate of the general average rate of operation by the independents is difficult. The common view seems to be that the independents are not operating at an average of over 50 per cent. In slack times it is a common practice for a mill to close for a time, to allow orders and specifications to accumulate for a moderately full run, and it is considered probable that many mills will seize upon the last fortnight of the year as a good time in which to close. Thus the year may end with the independents almost altogether closed. As for the Steel Corporation, it looks as though it would be able to maintain a moderately full rate of operation for months even if there is no improvement in the general situation.

Manufactured Steel

Declines in the hot rolled products are naturally working their way through to the manufactured products. Cold finished steel bars have come down from 4c to 3.60c. Bolts and nuts have been reduced various amounts, averaging about 20 per cent. Rivets have not been formally reduced. For some time there has been shading of the old official price of 4.75c to 4.50c and 4.35c, but a reduction in keeping with the declines in hot rolled steel is expected to carry the market down at any rate to 4c. Chain is still nominally at 7.25c.

Hot and cold rolled strips have been reduced a cent a pound from the old official price and a half cent from the market actually existing in the past two or three weeks, the new prices being 4c

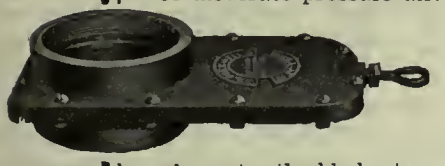
New Air-Tight Blast Gates

will help you maintain the safety, economy and efficiency so essential in the operation of furnaces and other appliances using low or moderate pressure air.



THEY ARE SAFE— because they are ruggedly built of only a few simple parts; the blade stays fixed in any position and by a slight pull of the handle is easily adjusted to give the blast desired.

THEY ARE ECONOMICAL—because the initial cost is small; the simple construction eliminates wear and tear.

THEY ARE EFFICIENT—because careful machining makes them AIR-TIGHT; they afford the full area of the blast pipe, in striking contrast to a stop cock; they are quick in operation; they can be placed in any position.

In short, these New Air-Tight Blast Gates possess all the advantages of stop cocks and valves, and have speciol features that tend for greater usefulness and economy.

for hot rolled and 7c for cold rolled. The producers did not expect to get any new business of consequence by the reduction, and state the reduction was made chiefly for the purpose of adjusting contracts on books at higher prices, so that customers would be free to file additional specifications.

Foundry pig iron is still quotable nominally at $37, valley, and perhaps this is so chiefly because there has been no inquiry to tempt producers to make lower quotations. On quotations made voluntarily by furnaces rather than in response to important inquiry Bessemer is down $2.50 to $35, valley, and basic $2 to $33, valley. It is possible that these prices will hold for several weeks. No great decline, at any rate, is to be expected until there is enough business developed to promote active competition. As matters stand the furnaces are rapidly running out of business and have nothing to do but blow out. Of the 13 merchant furnaces in the Mahoning and Shenango valleys seven are out and the six still in blast are referred to as being "on the ragged edge." Perry at Erie is out.

BUYERS ARE OUT OF THE MARKET

Special to CANADIAN MACHINERY.

May Come in at First of the Year if any Inducements are Held out to Them

NEW YORK, December 9.—(Special to Canadian Machinery).—Most of the large prospective buyers of machine tools, which includes the railroads and companies such as the General Electric Co., have advised machine-tool dealers and sales representatives that there will be no buying until after January 1. They do not even promise for a certainty that there will be buying at that time, but the intimation is given that if other conditions, such as credit and prices, are satisfactory they may do some buying early in the new year. The General Electric Co. has plans for continued expansion, but these plans have been held in abeyance for many months. Quotations have been received by this company in the past several months on scores of tools, which have not been bought, and if orders for the entire number inquired for should be issued early next year it would have a very beneficial effect in stimulating the market.

November was an exceedingly dull month, and there is even less buying so far in December. With the inventory period so close at hand, it is natural to expect that even urgent requirements will be put off until the new year.

Little has been heard lately regarding prices. There are so few buyers in the market that the subject is not brought up with the same frequency and insistence that prevailed a month or so ago. Machine-tool builders are principally concerned in getting their present orders shipped. There is a good deal of talk about an adjustment of wages for labor before the machine-tool industry starts out on a new price basis.

MANY CHANGES TO BE MADE IN BRITISH EMPIRE STEEL CORPORATION

A REPORT in a Montreal paper says that the British Empire Steel Corporation is to be dropped entirely. The paper goes on to say:

"The probability of this being the fate of the venture has been a subject of much discussion in financial circles for weeks past, but in circles close to merger interests no admission in the connection was available.

"It is now generally admitted both in Montreal and London circles close to the company that it will be impossible to carry out the financial arrangement necessary to the completion of the contracts with the various units of the merger, and that in consequence it will be impossible to proceed.

"On the other hand it is generally understood that an alternative scheme will be an arrangement to bring Dominion Steel and Nova Scotia Steel together, but all the other units are to be dropped.

"The proposition was one of the most ambitious ever undertaken in connection with Canadian industries, and the need of letting the matter drop will be heard with genuine regret by many Canadians who believed that as a constructive scheme it had many fine and attractive qualities, particularly with respect to the support it promised to bring from the Mother Country.

"The programme had been carried through up to the point where all that practically remained to be done was to bring out the issue of $25,000,000 of 8 per cent. preferred stock of the corporation, and the money market in London has been most unreceptive for a long time and the issue was put off from time to time in the hope that it would improve."

This report is not in keeping with one received by Canadian Machinery this week from one of the officials connected with the deal from the very start. He admitted that there were obstacles in the way which had prevented the underwriters from finishing their work, but those connected with the deal had committed their companies to it to such an extent that it would be impossible to call the deal off. It seems that the details will have to be worked out on a new basis as the figures used in the first instance have been found to be unsatisfactory. The official giving information to this paper did not know for certain when the deal would go through, but intimated that for the present there was nothing being done.

Equipped at Cost of a Million, Will Cater to the Needs of Western Canada

The first open-hearth reverberatory furnace in Manitoba recently commenced operations at Selkirk, about ten miles northeast of Winnipeg.

The plant, which represents an investment of about $1,000,000, is known as the Manitoba Rolling Mills, and its equipment is said to be of the most modern type, consisting principally of one 15-ton furnace, three 15-ton ladles, crane, dumps, molds, and other machinery. Electricity is supplied by the Winnipeg hydro-electric stations.

It is expected that the surrounding territory will furnish an ample quantity of steel scrap.

The fuel used by the new rolling mill is Canadian bituminous coal, crushed into 1-inch cubes, elevated into a hopper, passed through a dryer, and from there into a pulverizer.

Orders have been received which will engage the output for several months, it is reported, but shortage of labor, high freight rates, and the scarcity and high cost of raw materials imported from the United States are said to have hindered capacity production. It is expected that the output of this plant will supply in a measure the demands of the market in Western Canada and that additional units will be equipped as fast as business warrants.

MALLEABLE IRON MEN STATE CASE

A Basic Industry, and Its Worth Proved By Experiences During the Great War

Presenting a memorandum on behalf of the various Canadian manufacturers of malleable iron, F. L. Storey addressed the Tariff Commission. Mr. Storey pointed out that the American industries of a similar nature, with their immensely larger market, operate under a condition of mass production which is non-existent and unattainable with the Canadian foundry in sparsely-populated Canada. If the tariff were removed these United States plants could reduce the selling field of Canadian manufacturers by their competition. Another handicap against the Canadian foundry is that the laid down costs of raw materials are greater than those of the U.S. foundries. This extra cost arises from the duty which the Canadian manufacturer has to pay on pig iron, coal and fire brick and the extra freight to Canadian foundry points.

He submitted these figures in respect to the Canadian malleable iron industry: Capital employed, $2,605,000; wage roll (yearly), $3,410,000; output, $6,816,000; employees, 2,634. "This," he argued, "is a key industry, and the war has taught each country the necessity for its protecting and preserving its key industries."

Six Examples of Simple Chucking Devices

Chucks for Machining Small Washers, Facing Rough Nuts, Machining the Ends of Short Threaded Parts, Drilling Small Holes at Right Angles to Main Axis, and Other Parts

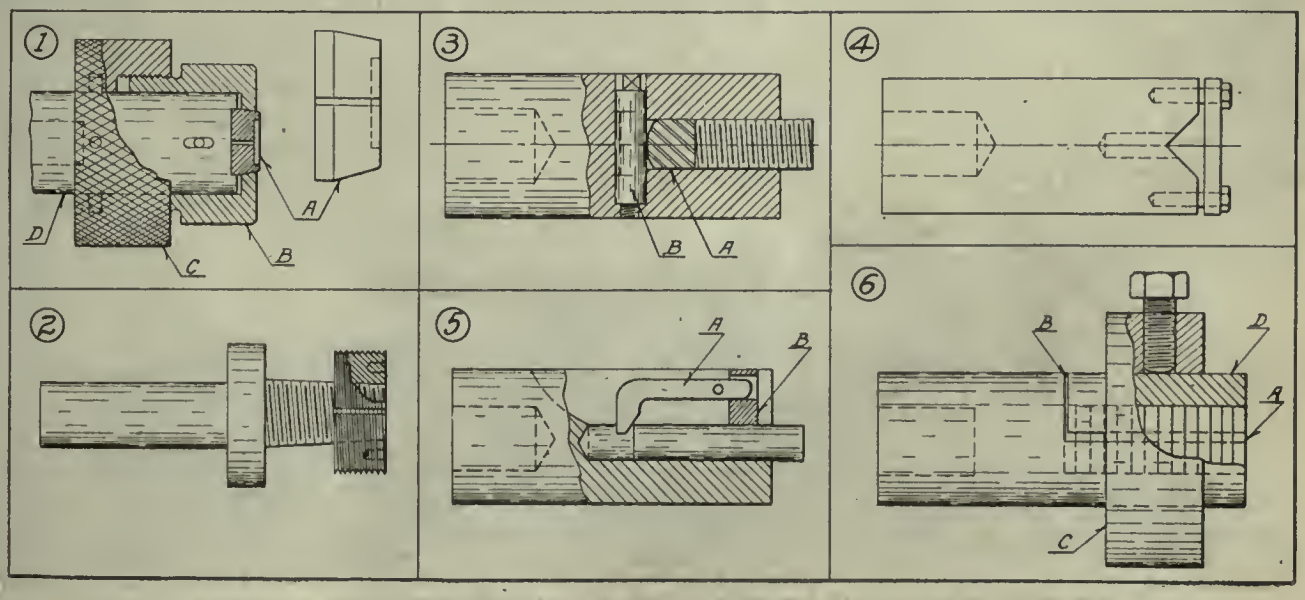
By F. SCRIBER

DRAWINGS of a number of chucking devices are here shown. These were originally designed for lathe use, but slight modifications would make the same adaptable for turret or screw machine service. The chuck shown in Fig. 1 is used for machining small washers on the face. It consists of a spring holder A, bored to take the washer and split in one place only. The piece B is a sliding fit on the body D, and is threaded to engage with the knurled tightening nut C. This nut is grooved in the shoulder at the rear. A hole is drilled in line with this groove, so that when the nut is in position on the arbor, the locating pins may be driven into the arbor, thus allowing the nut to turn freely without any lateral movement. Work of any desired diameter, within the range of the chuck, may be done by making suitable spring holders. This particular type of chuck has a comparatively long life as it does not rely on screw threads for maintaining its concentricity.

The piece shown in Fig. 2 is more in the nature of an arbor than a chuck. It was designed to be used in facing a large number of black or rough nuts square with the thread. In order to do this it was essential that the nuts should tighten up on the thread and not against the opposite shoulder. It will be noted that the arbor proper has a slightly tapering thread on which the split collar is located. The nuts are threaded on the collar by hand and the collar is turned by means of a pin wrench, until the nut is firmly held. When machining the end of short threaded pieces, threaded studs, etc., it is often difficult to get them off after the machining operation. The chuck shown in Fig. 3 was designed to overcome this trouble.

The work when screwed into the chuck, bears against the piece A (which is a sliding fit in the hole) and in turn, this piece presses against the pin B, which is inserted at right angles and with a nice turning fit, threaded on end and provided with a square on the other end for using a box wrench. The pin B has a portion in the centre filed in the form of an eccentric so that the work can be easily released by simply turning the pin after the machining has been performed. The small thread on the end of the pin B is simply to retain it in position. In Fig. 4 is shown a simple but serviceable chuck for use when drilling or boring small holes in round stock at right angles to the main axis. A chuck of this kind will take care of a great variety of work, such as the enlarging of holes or the turning of odd shapes in previously drilled holes.

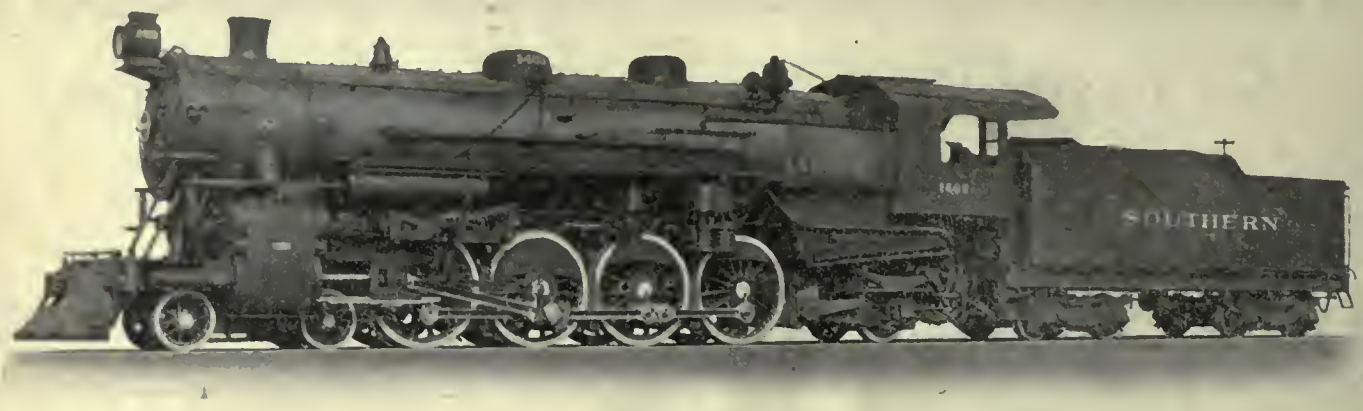
When a large number of short round pieces require to be centred the chuck shown in Fig. 5 will be found to be very handy. The chuck is bored to take the desired diameter of stock and is slotted on one side to enclose the lever A. Before slotting, a hole is drilled at the forward end to take the small brass pin B. This pin is provided with a slot in which the short end of the lever operates; this slot must not be cut too wide as there is a possibility of the pin falling out when work is removed, or interfere with the



THIS GROUP SHOWS THE SIX IDEAS; EACH OF WHICH THOUGH SIMPLE IS VALUABLE.

work when placing in the chuck. When pressure is applied to the outer end the inner end presses against the tail of the lever, thus forcing the pin B down upon the work. The advantage of this chuck is that the machine need not be stopped to change the pieces of work, as the work can readily be removed when pressure is released.

The chuck shown in Fig. 6 is used when drilling or reaming a large number of washers, several of these being placed in the chuck at the one time. When making the chuck the centre hole is first drilled and bored to the desired size and afterwards split as shown, so that the top half may be removed to facilitate loading and unloading. The ring C was bored to fit closely and drilled and tapped for the tightening screw. When loading the clamping ring is released and slipped back out of the way. In a chuck of this description the operator has a clear view of the work as the pieces are placed in the holder. All of these chucks can be made from discarded material about the shop and frequently eliminates the necessity of securing castings for the making of impromptu equipment.



Development of 8 Driving Wheel Locomotive

By J. SNOWDEN BELL

IN the December 2nd issue we touched upon certain phases in the development of the eight driving wheel locomotive. This article is the conclusion of the story. Readers have no doubt followed this development with interest, and it might be well to add that we secured the data from record No. 89 of the Baldwin Locomotive Works. Let Mr. Bell continue with his story.

A comparatively recent locomotive of the type, engine No. 19 of the Lake Superior & Ishpeming Ry. (Fig. 12) indicates the great increase in size and power which has been made in this type since its origin in 1864, and development in the "Consolidation" of 1866. This engine was built in April, 1916, and its dimensions are as follows: Weight, 268,000 pounds; on driving wheels, 238,000 pounds; cylinders, 26 x 30 inches; driving wheels, 57 inches diameter; boiler, 88 inches diameter; heating surface, 3643 square feet; (superheater, 844 square feet); grate area, 58.7 square feet; boiler pressure, 185 pounds; factor of adhesion, 5.25; maximum tractive power, 56,000 pounds.

"Mikado," 2-8-2 Type, 1897

The next succeeding step in the development of the eight driving wheel locomotive was the addition of a two-wheeled trailing truck, this wheel arrangement characterizing what is known as the "Mikado" or 2-8-2 type, which was first applied by The Baldwin Locomotive Works in 40 engines built by them for the Nippon Railway of Japan, in March, 1897. The advantage of this type, in affording a substantial increase in boiler capacity, was immediately and generally recognized, and it has practically superseded the 2-8-0 type in heavy freight service. Many 2-8-0 engines have been rebuilt in conformity with the 2-8-2 type.

Fig. 13 represents a high power 2-8-2 type locomotive which is one of a lot built by the Baldwin Locomotive Works for the Chicago, Burlington and Quincy R.R., in June, 1917. This locomotive weighs 314,700 pounds; weight on driving wheels, 239,200 pounds; cylinders, 28 x 32 inches; driving wheels, 64 inches diameter; boiler, 88½ inches diameter; heating surface 4,465 square feet; (superheater, 1031 square feet); grate area, 78 square feet; boiler pressure, 180 pounds; factor of adhesion, 3.98; maximum tractive power, 60,000 pounds.

"Mountain," 4-8-2 Type, 1911

The latest design and probable limit of capacity of the eight driving wheel locomotive appears in the "Mountain" or

FIG. 12.—THIS ENGINE WAS BUILT IN 1916, AND IS USED ON LAKE SUPERIOR AND ISHPEMING RAILROAD.

FIG. 13—A HIGH-POWER 2-8-2 TYPE LOCOMOTIVE BUILT FO R THE CHICAGO, BURLINGTON AND QUINCY RAILROAD.

4-8-2 type, in which a four-wheeled leading truck is substituted for the two-wheeled truck of the 2-8-0 and 2-8-2 types and which was originated by the American Locomotive Co., in locomotives built by them for the Chesapeake & Ohio Ry., in 1911, for passenger service, in which they have hauled trains of 645 tons over grades of 1.82 per cent. at a speed of 26 miles per hour.

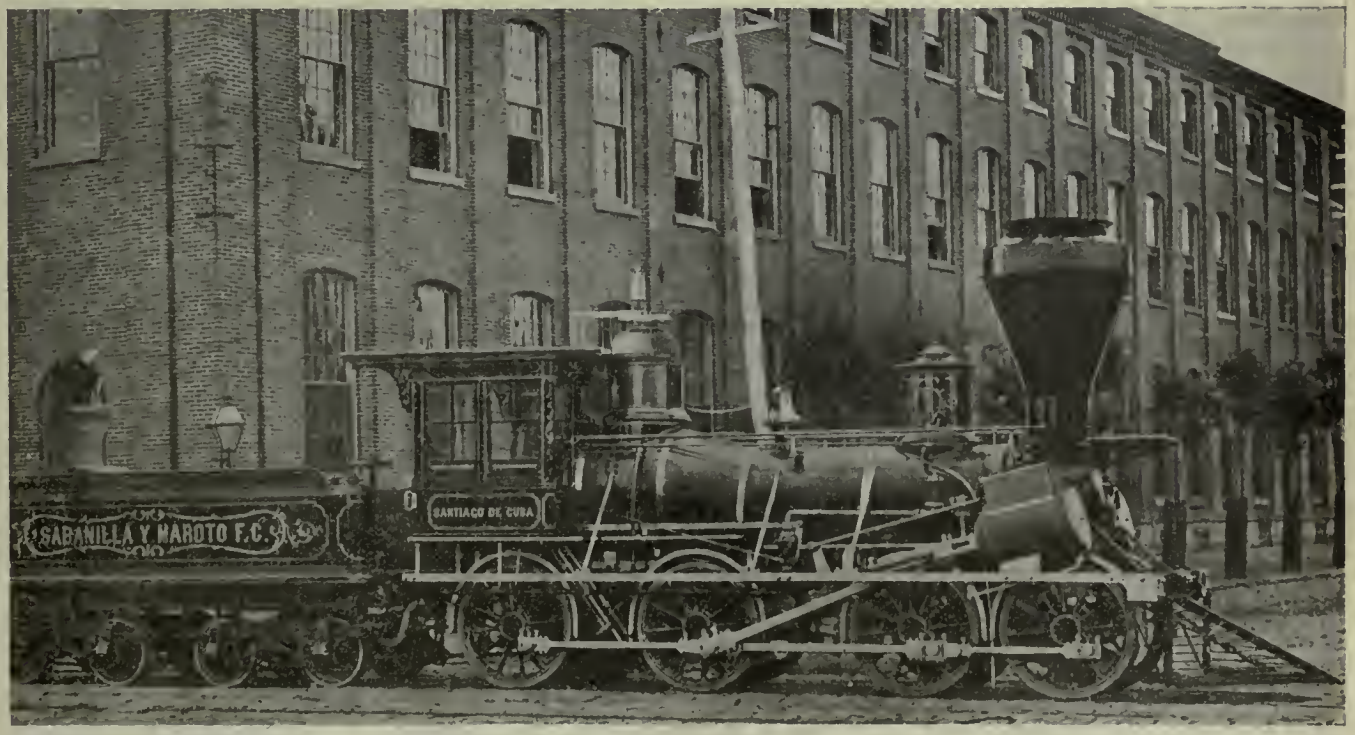
The heading of this article illustrates one of a lot of locomotives of the type, built for the Southern Ry. by the Baldwin Locomotive Works in 1917. The principal dimensions are as follows: weight, total, 314,800 pounds; weight on leading truck, 53,800 pounds; weight on driving wheels, 209,800 pounds; weight on trailing truck, 51,200 pounds; cylinders 27 x 28 inches; driving wheels, 69 inches in diameter; boiler, 76½ inches diameter; heating surface, 3,668 square feet; (superheater, 942 square feet); grate area, 66.7 square fet; boiler pressure 190 pounds; factor of adhesion, 4.38; maximum tractive power, 47,800 pounds.

Except as to the greater safety of a four-wheeled leading truck at comparatively high speeds, and the capacity of a slightly longer boiler, the 4-8-2 type presents no substantial advantage over the 2-8-2, while on the other hand, it is subject to the objection of reducing the proportion of weight available for adhesion. Thus, the 4-8-2 type for the Southern Ry. carries 66½ per cent. of its total weight on driving wheels, while in the 2-8-2 type for the Burlington, illustrated in Fig. 13, the proportion is 76.0 per cent. The speed of passenger trains on mountain grades is not so high as to render a two-wheeled leading truck unsafe, and the possible increase of boiler capacity in the 4-8-2 type is not great.

The exceedingly great increase, shown by the foregoing review, in the size and power of the eight driving wheel locomotive over the Baldwin direct coupled engines of 1846, which may properly be considered as the earliest instances of the designs that were adapted to continued practical railroad service, has, of course, been accompanied, and rendered economically available by the numerous improvements in structural features and accessories which have been embodied in locomotives of the various other designs that have from time to time been introduced. The advantage of the design, as practically perfected in the improved types in which it has been applied, is unquestionable, and other than for exceptional conditions of service it will doubtless continue to be the preferred one for freight train work.

AN EXPLANATION

Through a regrettable error in our Advertising Copy Department engravings were taken from an article on Die-Castings, which showed examples of work done by the Franklin Die-Casting Corp., and the cuts were used in the advertisements for the Fisher Motor Co. The Franklin Die-Casting Corp. have written us stating that they are the originators of the process described in the article, and that the Fisher Motor Co. are in no way connected with the Franklin Die-Casting Corp. either by license or otherwise. We have pleasure in making this explanation and correction.



AN 8 COUPLED, FLEXIBLE BEAM TRUCK LOCOMOTIVE BUILT FOR SABANILLA AND MAROTO RAILWAY, CUBA, IN 1866. THE WEIGHT IS ABOUT 65,000 POUNDS.

Canadian Firms Discuss Their Production

Some Firms Find That the War Shop Still Exerts an Influence—Many Forces Have Been at Work in Recent Years to Break Up the Organizations in This Country

TO what extent has production fallen off in Canadian factories during the past three or four years? This paper put the question to a number of manufacturers, holding that if such were the case a remedy should be found, and if, on the other hand, production had not dropped off, it was not right that the Canadian workmen should be credited with having anything to do with such a condition. Some of the information was secured a few weeks ago and conditions may have changed somewhat since, but there is, in the main, a very fair analysis of the whole situation.

One Kitchener shop says: "Unfortunately we are not in a position to give you much information regarding this point, as our line of manufacture is such that we have no accurate means of determining just what the production per man is, as compared with years past, and are not able to give you particulars regarding this point.

"The situation with us, however, has been such that the housing accommodations in our city were totally inadequate and we have been obliged to employ a great many young unmarried men. These we have found would not work steady, owing apparently to the high wages which they were receiving. This has caused us a great deal of trouble and has reduced our production very materially.

"With the change, however, in labor conditions we find a better class of help available and are gradually replacing men of this type. We regret that we cannot give you any more information, but shall be interested in the results which you obtain from various firms from whom you are asking for information along this line."

Goes Over the Whole Situation

One Canadian manufacturer discussed the matter at considerable length. He has been a careful observer of passing events, and looking back over a period of several years, says:

"You have raised a large question. Almost any manufacturer will tell you offhand that production per man has fallen off sadly in the last year or so, but it is hard to lay one's finger on the exact reason for this. General Booth, on his return to England after a world tour, recently stated that what the worker wanted, in his opinion, was not a bigger wage, but the opportunity at all times to do less work. From my own observation, I am in agreement with the General.

"Plants have changed so in the past six years that we have literally no standards to guide us in an impartial judgment of what constitutes a real day's work. Before the war there was always some record which had been set up at one time or another by a highly skilled operative; this passed into shop history, but became a standard by which performance and pay were unconsciously regulated.

"Then came the shell business, with the consequent breaking up of organizations by enlistment and the bigger pay offered in the new shell shops. We have all been obliged therefore, to enlist any help we could get hold of to keep the plants running at all. The men who were known as steady workers before the war were absorbed immediately and gladly, but the waverers before became the shirkers after. This, mark you, was not entirely their own fault. They had lived for five years under abnormal conditions, having no responsibility, just doing what they were told to do, and living from day to day. They had no fear of not being clothed or of having their meals at some time or other.

"When the trade boom of June, 1919, came along, factories were just beginning to settle down with a fairly complete organization. The motor trade in particular, and allied industries also, were in dire need of all sorts of help and commenced to offer inducements to get men into their shops. This again broke up the working forces of all factories. Here in Western Ontario we felt that we were merely feeding the factories of Detroit. The labor turnover was out of all proportion to the force employed, and most factories were left with the mass of their workers half trained, and consequently, production per worker was again cut. Here again the question of standards enters. With an almost new force, there can be of necessity no actual standards. It is a matter of laborious training to secure any.

"It is unfair to compare the production of semi-skilled men with that of old workers in any given industry. However automatic machinery may be, there still enters the personal element and aptitude to any particular job. But in our own particular industry, we are only getting a little more than half the production we were before the war on the skilled and semi-skilled jobs. We introduced a bonus scheme, but the necessary proportion of labor to output was never attained.

"Perhaps the experience of this factory has been unusual, as all our help has had to be trained from the raw, so to speak, but the results have been as noted above and production has been far below that of pre-war days. I believe the men and women we employ are doing their best, as far as they know, but for the reasons briefly outlined above it is not a very good best. I do not believe that the majority of our helpers are wilfully trying to hold up production, but the era of higher wages has unsettled them to the extent that they are not anxious to learn thoroughly any particular job.

"With regard to coming into close contact with men, in normal times this is not difficult in small towns, as the outside interests of both employers and employees move along the same lines. In lodges and churches, sports and clubs, they meet on the same ground and have very often been brought up in the same school. But latterly we have had a large percentage of "floaters" with whom we have nothing in common. These men do not enter into the social activities of a town at all. An employer has therefore no means of judging these men except by their performance in the shop, and for some months can get no 'line' on them."

Labor Is Inefficient

A manufacturer in the steel trade in one of the industrial centres of Quebec tells his experience as follows:

"Our experience is and has been for some time that labor is very inefficient; production per man has fallen off from 30% to 40%, and is about on that basis now as compared with pre-war conditions. We have seen it stated that in some plants production per man was increasing, but this has not been our experience. We can see no improvement, but possibly it may reach us later. Conditions with us are probably about the same as they are with other manufacturers. Labor is inefficient, careless and independent. Spoilage is much greater than normal because of carelessness of labor.

"We have made use of no particular method except to at all times talk with our men on the desirability of increasing output and becoming more efficient. We do not pay bonuses, but advance our men regularly as they improve. There is no reason that we know of why production should be more difficult, in fact everything tends to the contrary, as we are always on the lookout for new machinery and new tools, and our plant is probably the best equipped plant in Canada for the manufacture of the line of goods that we market. Shop conditions could not be improved; living conditions are above the average. We

are inclined to think that with the gradual decline in the cost of living, and the fact that a great many plants are reducing their forces, in a short time there will be a surplus of help and that they will be more efficient."

Piece-Workers the Same

A St. John, N.B., firm, discussing the matter, has had the following experience: "In our finishing shops we could not say that we have had occasion to find any decrease in production per man, as all our work of this nature, to a large extent, is handled on piece work; the same also applies to our moulding shop. However, with our laborers we have noted a remarkable decrease, but at the present time, indications seem to point for an improvement in this class of work."

Supply and Demand

This firm is in a good industrial district in Ontario and the experience would no doubt be that of many others: "In a plant the size of ours we have not the figures to prove the actual falling off in production that may have taken place in the last number of years. In parts of our plant where a premium is paid for increased production the falling off is not so noticeable, but in the parts of our plant where we have not been able to do this we get considerably less production per man than we did before the war.

"The situation arose, of course, out of the very great need for men during the war and the lack of a sufficient supply. We think that the condition in our plant is a little better now than it was a few years ago, owing possibly to the fact that business is not so brisk and we may need to lay off help before many months have passed. They seem to sense things such as this and naturally we get a little better effort on their part.

"The whole question, to our minds, simmers down to a question of supply and demand and we think chances are that within the next six months all concerns in the country can expect much more efficiency than they have been favored with before."

Piece-Work the Best

A Nova Scotia firm believes that piece-work is the best plan to keep production up, and gives its experience as follows, this being an engine and boiler industry: "We would advise that in our opinion there has been a decided slowing down of the production per man as compared with pre-war conditions. We have found that this can be remedied and almost completely overcome by introducing piece-work and offering the men an inducement for speeding up. We are introducing piece-work now in almost every department, and the result has been most surprising. In some cases we have actually reduced our costs to one-third of that previously prevailing by this means."

Compares 1918 and 1920

This firm is in the foundry business in a Quebec centre and apparently has taken some trouble to keep in touch with past performance on the part of its force. Its experience is as follows:

"In reply to your letter we wish to say that a few days ago we took up the question of production of our plant for the month of August in the years of 1918 and 1920. This showed a falling off of nearly 20% and this indicates that there is considerable truth in the statement which seems to be general that labor is not producing to the same extent as prior to the war. The production in a foundry producing miscellaneous castings is naturally affected by the class of work handled in the periods under observation, and as we are now making more miscellaneous castings than in 1918, we think that this is one reason for the falling off in production. We have no special methods to secure better effort on the part of the workmen, but we arrange as far as possible to pay them on a piece-work basis, and find that production on a piece-work basis will vary from 10% to 50% over day work. Generally speaking, we are free from labor troubles. Ours is an open shop and whilst we pay union wages and better in some cases, we do not deal with the men collectively.

"International organizers or agitators have endeavored at different times to stir up trouble, but the majority of our men are satisfied with the working conditions and will not listen to them. We cannot truthfully say that there is any tendency on the part of our workmen to hinder production. We may have some employees who hinder production by laziness, but not by intent."

Still Feels War Influence

The war shop is still felt in many places, and it has not been eliminated as a disturbing element where fine work is necessary. This firm operates its Canadian plant in Quebec. The general superintendent discussed the matter of production at some length:

"It is pretty hard for me to give you any figures regarding this subject. I do know that the production was increased in all departments of this plant, but whether it has also been successful from a monetary standpoint is a question that I am not in a position to answer. We feel that the production in any plant can fall off just the same as the quality of supervision will fall off, and not come up to standard, and when this latter condition exists, the plant will fall into a listless condition and if not wakened up by those in direct touch with the figures, will gradually fall into a state where it is almost impossible to again reach the old standing.

"My reason for the loss in production, in a great many plants is that the plants are now full of war-time mechanics and other workmen who served their apprenticeship and became master workmen in one operation. The regular men of a great many plants were influenced to change from one plant to another, to sell their labor to the highest bidder so that the old-time mechanics were scattered to the four winds, some of them never returning to the plant in which they worked before the war. When the different plants returned to their standard productions, it was a case of a few men who were left out of the original organization, having to break in a great many, who I think are only apprentices. We are not entirely free from this condition and it requires that we keep an active watch on all operations, feeds, speeds and other methods pertaining to rapid production, or we would have to agree that we are losing ground. On the contrary, however, there are three conditions: first, standing still; second, going back to failure, and the third, going on to success. And I for one am unwilling to admit anything in connection with our plant excepting the last condition, because I believe if I had to I would be admitting that this company was working on the down and out course."

A Good Word for the Men

An Ontario firm, making several lines in the iron, steel and metal industries, believes that some care should be taken about statements made regarding the way in which men abuse shop privileges. This firm holds that in 85 per cent. of cases the men are trying to be square.

"It is a most difficult matter for us to answer with any degree of accuracy. We have made very considerable changes during the past five or six months which makes it a very difficult matter to make positive statements along the lines your letter asks information upon. My own judgment is that in any factory there are a certain number of men, say 15%, who are out to get as high a wage as possible, for as small amount of work as they can get along with, giving in return, but the other 85% are good, decent chaps who want to do the fair thing and give a return for the money paid them.

"We believe this applies to our own staff here and we naturally do not want to be advertised as giving out the information that production per man has been universally less during the past years. Hours of labor have been considerably shortened, while wages have been increased, and the cost of production to manufacturers has, without doubt, risen on a given amount of the company's product. We have consequently been compelled to assess our customers a higher price for this reason, and also for the reason that the same principle has made the cost of our materials higher or at least has been one factor in doing so."

Rope as a Means of Power Transmission

English Practice Regarding Rope Drives—The Three Versus Four, or More, Strand Ropes—Spiral Elongation, the Life of Rope, Rope Guards, and Effect of Moisture.

By J. MELVILLE ALISON

THE subject of ropes for power transmission is one that has received close attention in England. In fact engineers in that country have given closer technical and practical consideration to the subject than we have perhaps on this side of the water. For this reason we append the following article which was presented before the Engineering Institute of Canada with an object in view, viz., to create interest.

Features of English Practice

The outstanding features of English practice may be briefly stated as follows:

(1) Cotton has entirely supplanted any other material for transmission work in England—manila is of the dim and distant past.

(2) The ropemaker is consulted as to plant lay-outs speeds, sheave diameters, centres, grooving, etc., and his opinion is deferred to.

(3) Guarantees of maintenance are required and given in almost all installations.

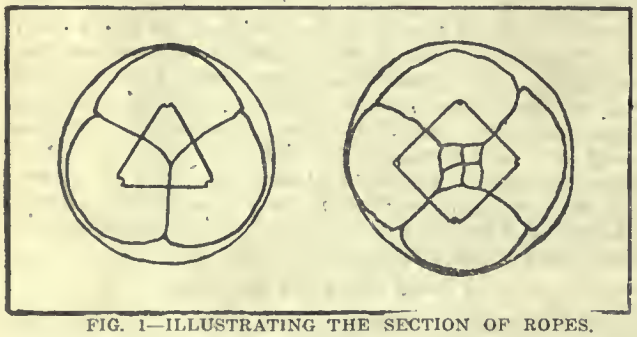


FIG. 1—ILLUSTRATING THE SECTION OF ROPES.

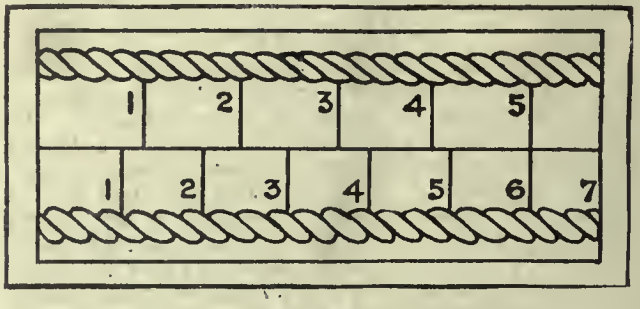

FIG. 2—SHOWING SECTIONS OF SPIRAL ELONGATION.

(4) The manila and steel rope manufacturers employ cotton ropes for transmitting their power.

(5) The efficiency and longevity of cotton ropes have commanded the employment of this material in the manufacture of transmission ropes.

In discussing the question of cotton or manila for transmission ropes, one must not lay too much stress upon initial cost, for although cotton is dearer than manila, its superior resilience, grip and groove impact add so greatly to driving force that up to one-third more horsepower may be transmitted. Further, its prolonged life being reckoned at approximately five to one will reduce apparently excessive first charges to an insignificant item.

Three versus Four (or More) Strand Ropes

Rope of three, four, or even seven strands is sometimes employed, but since the contest lies mainly between the three and four strand, it will suffice to demonstrate the advantage held by the three-strand over the four or any other construction.

Examining the section of a three-strand rope, Fig. 1, we obtain an equilateral triangle by connecting the centres of each strand, demonstrating the triangulation of the strains, a principle adopted by all engineers in erecting angular constructions, such as bridges, etc. In a rope of this construction we have a trinity of elastic spirals, so supple that they will bend to and fro without disturbing their formation. With the four-strand rope, adopting the same method of connecting the strand centres, we obtain a square and an illustration of the parallelogram of forces from the four centres. Again, the four-strand rope cannot be constructed without a supporting core, and since this is indispensable to its construction, its collapse must mean the dislocation of the whole structure, and as the core represents only about one-fortieth of the area, it may be reasonably assumed that the superior force exerted by the alternate contraction and extension of the spiral as the rope passes over the sheaves, must tend toward the breaking up of this core, the period of endurance being limited by its elasticity and the tension at which it is laid. This is what actually takes place.

Spiral Elongation

This will probably be the more readily grasped by referring to Fig. 2, which shows a three and four-strand rope in parallel, with the turns of one strand indicated by the figured lines. Thus the turns of the three-strand gradually gain upon the four in the proportion of one in five, or, in other words, six turns of the three-strand occupy the space of five turns on the four-strand, i.e., in ropes of the same thickness. The strand spiral of a seven-strand rope is nearer the straight line, being almost double the length of a three-strand rope.

It will, therefore, be acceptable that the medium engaging the greatest number of turns should prove to be the most resilient and more capable of disposing of the shocks and stresses set up, for instance, in rolling mill work, than any other. Again, as affecting the bending capacity of the rope, another important difference is observable—only two strands appear between every turn of a three-strand, while three occupy the spaces between every turn of a four-strand.

Longevity of Cotton Ropes

As to the life of cotton ropes, much, of course, depends upon their size and the conditions under which they have to work. All things being equal, durability may be gauged by sectional area, and the most economical diameters range from 1½ to 1¾ inches, more of the latter being use in England than any other size. For rolling mill work, however, it so often becomes a matter of sheave widths that 2 inch ropes are generally used. A remarkable case of longevity may be mentioned of twenty-four cotton ropes, 1¾ inches in diameter, employed to transmit 820 horsepower at a velocity of 4,396 feet direct from engine flywheel, 28 feet in diameter, in a Lancashire cotton mill. These were fixed in October, 1879, and are still running in 24-hour a day service, a period of over forty years. Another set has been working twenty-eight years on an average of 20 hours per day, and appear little the worse for wear.

Such cases of longevity lead to the conclusion that fatigue of material due to constant activity does not readily manifest itself in well-make cotton ropes. Their quick recovery from driving strain is suggested as the cause, since they pull down on the working side and bulge out to their normal diameter immediately upon passing to the idle or slack side of the drive.

English and American Systems

There are advocates of both systems

on this side of the Atlantic. We in England are almost exclusively under the English multiple system, and have little experience of the American continuous method. Our education, however, in this latter has been considerably advanced during the last six to ten years on this side, and it has been amply demonstrated that good cotton rope on the continuous system will pay for itself.

In England we are satisfied that the multiple rope system is the better in all-round practice. Immunity from stoppage is the most important factor, since it is seldom that more than one rope gives way at a time. The offender may be laid aside to await a favorable opportunity for replacement. An admission made to me by one of the leading authorities of the American system was that while all his experiments had been made with manila rope, he had the impression he could get still better results with a good cotton rope.

A drive has been erected for the Armstrong-Whitworth Company of Canada, Ltd., at Longueuil, Que., in which the sheaves are 108 inches and 72 inches in a rolling mill plant, with only 15 foot centres and grooves for twelve 1¾ inch ropes, which allows for only 7 feet 6 inches between rims. This drive was fitted under guarantee of maintenance from the ropemakers, who originally were consulted on the scheme.

Over Roping

Over roping certainly retards efficiency. The fault sometimes manifests itself by the slack changing with the pulling side, and at other times by the ropes travelling across the grooves or even leaving the pulleys altogether. When such troubles arise it is best to remove one or several ropes if need be without interfering with the splicing. Pass them over both pulleys and tie them well back to avoid revolving shafts. They can then be readily put back to work as the others give out. We have known instances where half the original number were taken off before satisfactory driving was obtained. This state of things frequently arises, even under fairly regular loads, when actual requirements come below the calculated power.

Over or Under Driving

While it is, and has been, generally accepted that the slack side of the drive should come on top, this position is not always obtainable, nor is it under all circumstances desirable. With an erratic or fluctuating load such as obtains in rolling mill practice, we recommend the slack to come on the bottom. The variable load of the mill tends to set up considerable oscillation in the ropes, and if the slack is above, may cause the ropes to ride or even jump off the sheaves. On the other hand, if the slack is below, any tendency of the rope to wander from its appointed track held very largely in check by the pull on the tight side, also gravity and the weight of rope will control the oscillations.

Rope Guards

If, however, ropes persist in wandering from their appointed track, we recommend the erection of a rope guard, in comb fashion, which should be placed approximately 10 per cent. of the centres away from the driven sheave. In rolling mill practice in England this is very freely adopted.

Sheave Diameters

Sheave diameters have a very important bearing upon the question, and while in England the minimum standard is taken as approximately thirty times the diameter of rope, in America forty to fifty times is accepted.

This, however, is largely a question of speeds to sheave size, as, for instance, a ½ inch rope will run comfortably over a 4 inch sheave at 1,000 revolutions per minute, a 1 inch rope over a 22 inch sheave at 3,000 revolutions per minute, and it is only when the speed rises to 5,000 feet per minute that we meet the thirty times rule for 1 inch rope.

Here, again, cotton scores over manila, since its softness readily admits of superior bending properties, while the native harshness of manila and almost entire absence of resilience compel a higher minimum sheave diameter to which ropes of this material can be bent over.

Centrifugal Force

Groove impact also acts in opposition to centrifugal force, which has proved so potent a factor in belt driving, that whatever is done by way of compounding with narrower belts, adhesive dressings, or squeezing out the inevitable air-cushion, it will assert its retarding influence at a velocity fixed roughly at about 3,000 feet per minute, when the power calculated on the basis of width must be discounted in proportion to the increase in speed.

As effecting the rope drive, however, many tables are compiled whereby a steady decrease of transmitted power over 4,800 feet per minute is shown, until we find ropes at 7,000 feet capable of transmitting only half the load of the same rope at 4,800 feet.

Effect of Moisture

Cotton ropes are also less susceptible to atmospheric changes than manila, for the reason that moisture more readily evaporates through the fibres, thus rendering them practically immune from internal mildew which so often is apparent in a discarded manila rope.

Inter-Stranded Cotton Driving Rope

Allowing the claims in favor of the three-strand rope, without further advocacy of the general principle involved, it may be logically contended that if such a rope possesses constant equality throughout, if the yarns are equal in counts, number, tensile strength and tension, each one following its appointed track without deviation, and are all of the best procurable quality, then we have arrived at a point bordering on perfection in the making of driving ropes, and their manufacture and application has been a close study for over fifty years.

This rope is made expressly for power transmission from the finest selected American yarns. Each of the three strands is made up of a succession of sheaths or layers of yarns, which may be peeled off until the centre thread is reached. The rope is machine built, under hydraulic tension, so that a perfect and combined tension is secured to each thread, from the moment these threads are led to the machine. The crinkling effect to be found more or less in all rope made by the ordinary method is thereby eliminated.

As previously mentioned, the triangulation of strains is secured in three-strand ropes, and in this particular rope is maintained to the individual threads. In effect this construction means that with the rope at work each thread takes its relative proportion of duty, and again in wearing only the external layer will show abrasion, leaving the next layer intact. This feature is of significant value, since there are many instances where, say, a 1¾ inch rope, after years of work, is reduced in diameter, but has still sufficient life left in it to enable it to be removed to a drive where ropes of about 1½ inch diameter may be in use.

There is no limit to length in constructing this rope other than may be controlled by convenience in transportation.

Splicing

All that has been said relative to the making of cotton driving ropes and their application to transmission of power would be of little value without some reference to the question of splicing.

This is so important to the well-being of the system in general that rather than have installations spoiled by indifferent workmanship expert splicing mechanics, properly trained to this duty, are sent out from England to all parts of the world. We have experimented with different devices of metal and other couplings, with a view to dispensing with splicing, but nothing has yet been found which, in England, would be considered against the long splice. This is usually calculated at about eighty-two times the diameter of the rope.

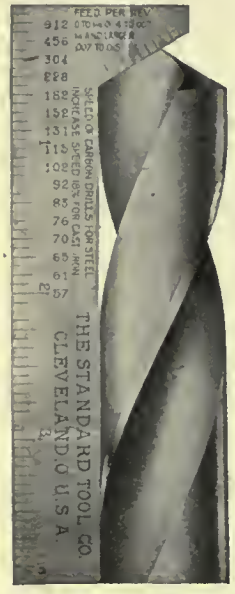
Can a Twist Drill Live up to its Reputation

It Can, and Will, if You Give It a Chance—Make Sure the Angle of Cutting Lip is Correct—See That the Clearance and Centre Angles are Right, Also Study the Data on What Will Happen if You Are Not Careful Enough

By H. WILLS

WHEN considering the precautions taken in the various operations in the making of a twist drill from the first laboratory test of the steel bars to the final inspection, it is a pretty safe conjecture that if a drill gives trouble some of the conditions surrounding its use should be investigated.

Twist drills will stand probably more strain in proportion to their size than almost any other tool, and a very large percentage of drill troubles could be eliminated were proper attention given to grinding the points. The form of the drill point controls the rate of production, accuracy of the hole, frequency



MEASURING LENGTH AND ANGLE OF CUTTING LIP.

of necessary grinding and the very life of the drill.

If the illustrations and instructions in this article are followed religiously, a uniform and satisfactory result will follow to an extent hardly appreciated by the average user of drills. In order to simplify the instructions contained herein we suggest that users of twist drills be supplied with a drill grinding gauge chart of similar nature to that shown.

Twist drills must be properly ground and run at a suitable speed and feed in order to do their work efficiently. With the aid of such a tool a skilled workman can attain the best results, this of course increasing the drilling production.

The tool as shown combines a gauge ground to an angle of 118 degrees and an accurate 4-inch scale graduated in 32nds and 64ths on one side and 16ths on the other. This gauge gives the proper angle and length of lip to the drills when they are being ground. The scale also contains a table of speeds and feeds

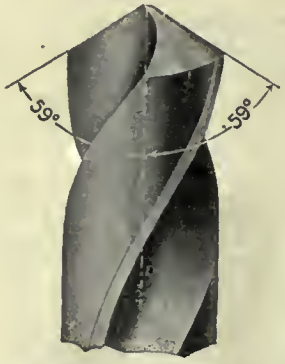


FIG. 1.—SEE THAT BOTH CUTTING LIPS ARE INCLINED AT THE SAME ANGLE.

for drilling steel and cast iron. Opposite each ⅛ inch mark is a number showing the proper speed at which to run a drill of corresponding diameter.

Length and Angle of Cutting Lip

Make sure that both cutting lips are inclined at the same angle with the axis of the drill and of equal length. The point angle of 59 degrees has been universally adopted as best suited for average conditions, and the result is shown at Fig. 1. To properly grind a drill, proceed as follows:

Correct Clearance and Centre Angles

In this case the drill point must have the proper clearance or contour of surface back of the cutting edges and such clearance must be identical on both sides. Approximately a 12 degree clearance

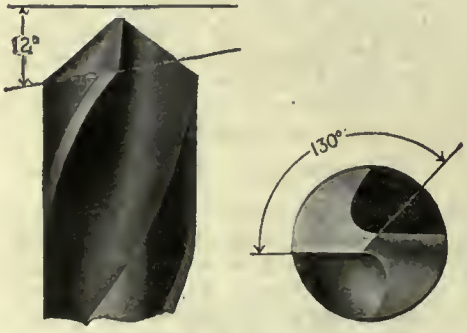

FIG. 2 AND 3.—WATCH THE DULL POINT.

angle, Fig. 2, combined with the centre angle of 130 degrees, which will give a constantly increasing clearance towards the centre, Fig. 3, has proven best for average conditions.

Incorrectly-Ground Drill Points

Some of the undesirable conditions resulting from drill points improperly ground follow:

When both lips are not ground at the same angle with radius, here is what happens. If both lips are not ground at the same angle with the axis, Fig. 4, one lip will fail to counteract the tendency of the other to spring away from the cut; consequently one lip will do more work than the other, which will result in its becoming dull more rapidly than if both lips were cutting equally, and it will be subjected to an abnormal torsional strain.

When Cutting Lips are Different Lengths

When the cutting lips of a drill have the same point angle, but are of differ-

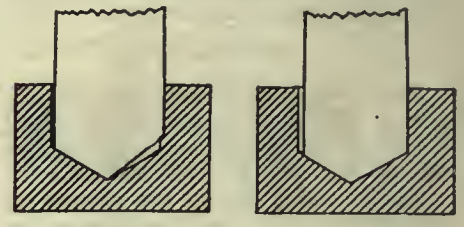

FIG. 4 AND 5.—POINTS TO WATCH.

ent lengths, Fig. 5, the point of the drill will be "off centre" or eccentric. As a result the hole will be oversize to an extent equal to double the amount of this eccentricity.

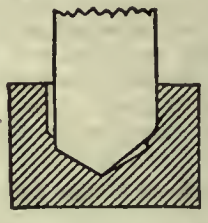

FIG. 6.—WATCH THIS DANGER.

If the drill point is ground both with lips at different angles, and of different lengths, Fig. 6, there will be a combination of the undesirable results already described.

Insufficient Clearance at the Point or Centre

Fig. 7 shows a side and end view of a drill with the proper angle of point (59 degs.), and the proper angle of clearance at the periphery (12 degs.), but with

insufficient clearance at the point or centre.

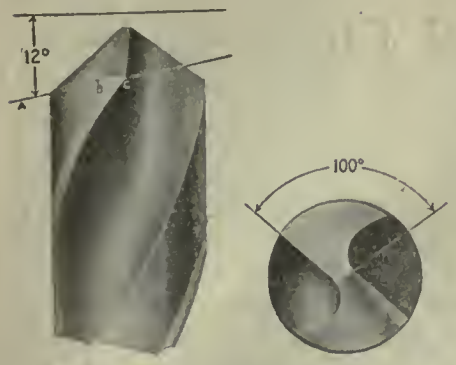

FIG. 7.—THIS IS A COMMON TROUBLE.

Fig. 8 shows a drill with insufficient clearance both at the periphery and at the centre. The line A-B-C is at an angle of 12 degrees, but there is no clearance immediately back of the cutting edges B-C, and the excess of clearance at the heel A-B is of no benefit.

Have You Experienced This?

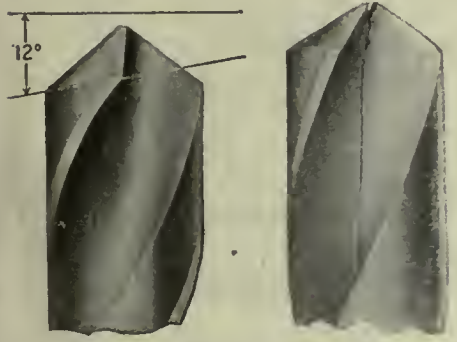
Fig. 9 shows what is liable to happen to a drill ground with insufficient clearance, especially if an attempt is made to obtain maximum production.

Fig. 10 shows a drill with a clearance angle of about 12 degrees but it does not have the proper contour back of the cutting edges. This manner of grinding leaves the cutting edges thin and weak, causing them to crumble away under heavy feeds.

Estimating Approximate Centre Angle

This gauge can also be used to approximate the centre angle. Although the included angle of the gauge is only 118 degrees, a centre angle of 130 degrees is recommended. The use of this gauge in the manner shown at Fig. 11 enables a very close estimate to be made.

Most twist drills are made with a gradual increase in the thickness of the web or centre of the drill toward the shank. As the drill becomes shorter



FIGS. 8 AND 9.—TWO COMMON TROUBLES.

and the web thicker, greater force is required to drive it. To overcome this, it is good practice to thin the web by grinding away the excess thickness, reducing it to its original dimensions. This grinding must not extend too far up the flute of the drill and care must be exercised that the cutting lips are not injured and that the same amount is ground out of each groove. Fig. 12 shows a drill with the web properly thinned. In Fig. 13 the grinding is excessive, leaving the web entirely too thin and liable to crumble. When this happens a split drill is practically inevitable.

Twist drills are made with a slight taper from point to shank so that the largest diameter is always across the corners of the cutting lips. This prevents the drills from binding in the work, when they are sharp. If the outer corners are allowed to become badly worn, the drills will bind and cannot perform satisfactorily. Whenever the outer corners of the cutting lips show wear, the drills should be re-ground and every particle of worn surface removed, or the drill will continue to bind and very quickly be damaged beyond repair.

In grinding high speed drills, care should be taken not to overheat them,

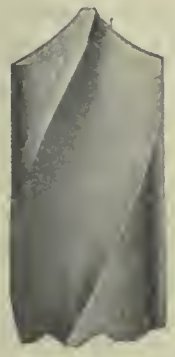


FIG. 10.—WATCH THIS DANGER.

and when heated they should never be plunged into cold water. Doing so is likely to cause small surface cracks, which reduce the efficiency of the drill and may result in serious damage to it.

Forcing the grinding on a wet grinder may also bring about the same condition.

If the suggestions for grinding drill points contained herein are followed and drills are run at the proper speeds and feeds, satisfactory results are practically assured. It is, however, hardly possible to do this grinding as accurately by hand as by using a good twist drill grinding machine, of which there are several on the market.

Broken or damaged tangs of drills are generally the result of an imperfect fit of the drill shank in its socket, which may be caused by a "worn out socket," "dirt or chips accumulating in the socket," or "bruises on the shank of the drill." In either case the driving power of the taper is reduced or destroyed, resulting in an abnormal strain being put upon the tang.

A drill of either carbon or high speed steel that can be filed is not necessarily

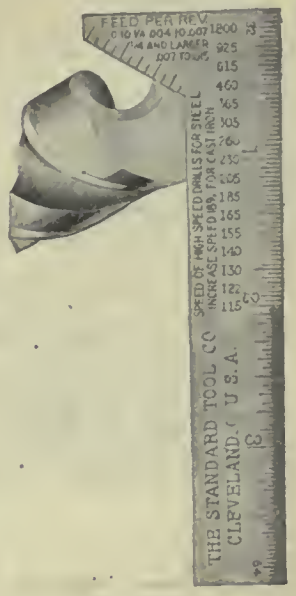

FIG. 11.—ESTIMATING THE APPROXIMATE CENTER ANGLE.

too soft for service; in fact, if drills were tempered so that a good file would make no impression, they would be entirely too hard for general use. If you have any doubt regarding the temper, try the drills in actual service.

Speeds and Feeds

There are so many conditions affecting drilling operations that it is extremely difficult to establish "hard and fast" rules for speeds and feeds. The tables given can be safely followed when drilling in commercial materials. Experience will enable the operator to determine what changes, if any, can be made from them. Assuming the drill is properly ground, when the corners of the cutting lips wear away rapidly it is an indication that the speed is too great. If the cutting edges roughen or break out in minute particles it indicates that the feed is too great.

In conclusion, let me say a word of caution regarding the use of very small drills. It is seldom that these are run at more than a fraction of the speed necessary to obtain the best results, and

FIGS. 12 AND 13.—CORRECT AND INCORRECT THICKNESS OF WEB.

excessive breakage is inevitable. These are delicate tools; be sure they run true and that the cutting edges are kept sharp. A fine grade emery stone is best suited for this purpose.

Would You Like to Receive One of These Scales FREE?

You can easily do so and at the same time add to your store of knowledge by entering our weekly contest of which details are given below.

The scale is 6 in. long and is made from finest quality steel. One side is marked in 32nds, the other side in 64ths. A table of decimal equivalents is also stamped on one side, and a table of tap drill sizes on the reverse side. This scale is well worth securing.

What You Have to Do

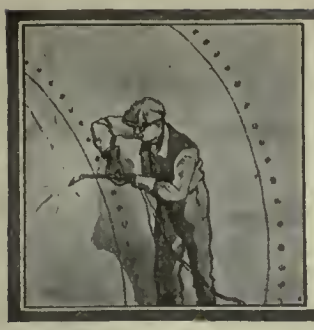
We publish every week a number of interesting facts or statements selected from the advertising pages for that week. The selections for this issue are given below. Read these through, then turn to the advertising section and see if you can pick out the advertisements to which they refer. The work is interesting, it will train your powers of perception and of memory, it costs you nothing, it will make you better acquainted with the various lines of machinery and tools in the market, and with perseverance you are bound to win one of these useful scales as a prize.

CONTEST FOR DEC. 16TH ISSUE.

Contestants are required to write us, stating to which advertisements we refer to in this number.

1—Something that can be procured with or without a certain attachment.
2—What to use if accuracy is of the utmost importance.
3—A machine that uses a herringbone gear drive to the spindle.
4—How to show a vast improvement.
5—Something said to be of unusual purity.
6—How to keep a shop clean and at the same time reduce insurance rates.
7—Something said to be more economical than coal.
8—A product that claims to have winning features.
9—A product that uses no electricity, and gives you very accurate results.
10—An important factor in every contract job that can be successfully mastered.
11—Something that is said to be safe, economical, and efficient.
12—A product that possesses strength enough to stand up under hard usage.

Closing Date for This Contest is January 6th



WELDING AND CUTTING

The Welding of Locomotive Fireboxes

Full Welded Fireboxes, Semi-Welded Fireboxes, Semi-Welded Half Side Sheets, and Full-Welded Half Side Sheets Are Taken Up in This, the First Part, of Complete Article on Above Subject.

Compiled by J. H. M.

IT IS not often that one is able to state in concise form the experience of two experts, but in the article to follow, dealing with the welding of locomotive boilers, the data contained therein have been gathered by Messrs. Geo. L. Walker and R. T. Peabody, both of the air reduction engineering service department of L'Air Liquide Society. This matter was placed before those interested in book form by L'Air Liquide Society, and through their courtesy the author is now able to compile this material in the form best suited for our purpose.

The oxy-acetylene process has stepped very much to the fore in late years, and has proven of great value in the repairing of fire boxes and flue sheets, principally because the joints are perfectly water-tight, while the speed with which the work can be accomplished adds still more to its value.

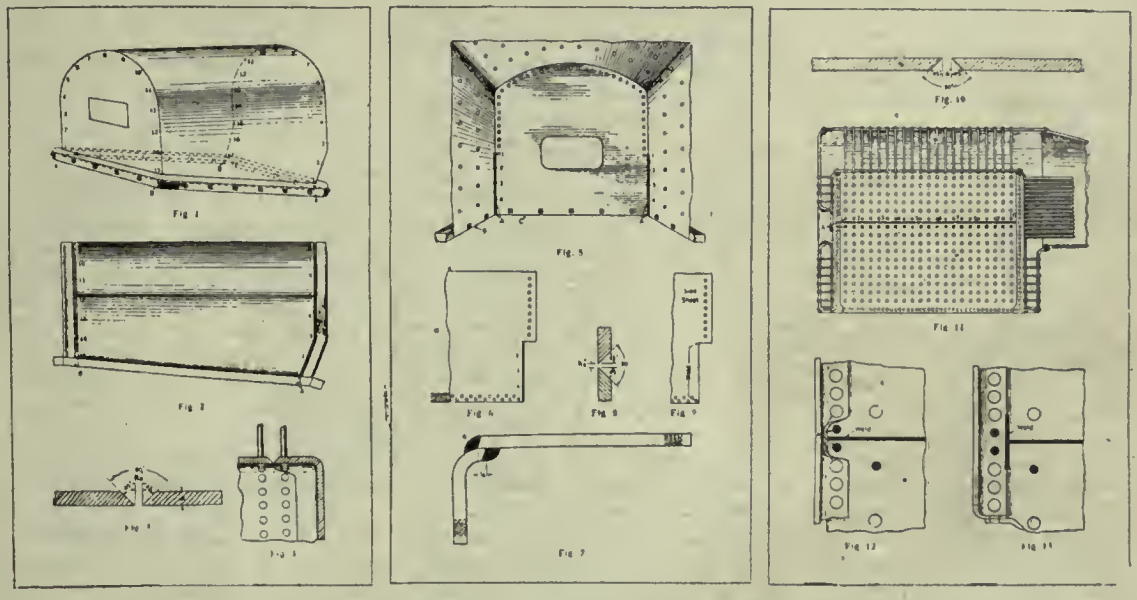
Failures have been recorded in the past but these have been traced to incorrect methods employed. This has been largely owing to inexperience on the part of the workman, or even utter lack of knowledge of the conditions. No one can make a success of welding until they become acquainted with the principles involved, choosing suitable apparatus, supplies, and so on.

General Instructions

The information to follow is given chiefly to assist the practical welder who might be or is working on locomotive boilers, and who is ambitious enough to read about what others are doing in that line. The methods advocated constitute the standard practices adopted by many railroad shops on this continent, and if carefully observed will ensure satisfactory results.

In the preparation of the work for welding, to ensure success it is necessary to observe five important things: First—The cleanliness of the sheets at welding seam. Second—That sheets are bevelled at a proper angle. Third—That sheets are in correct position. Fourth—That provision is made for expansion and contraction, and fifth—that you have suitable welding rods as filling material.

Before cutting a new patch, carefully inspect part to be welded and cut out all defective places, then cut only where there is a good foundation for the weld. When cutting out patches, carefully avoid cutting through stay bolts if possible. Do not under any circumstances cut out sheets or patches through old welds. For side sheets or three-quarter door sheets, extend new sheets at least one stay bolt higher; for crown sheet, one stay bolt lower; for patches, extend weld at least one row of stay bolts lar-



FIGS. 1 TO 13, INCLUSIVE.—TEXT DEALS FULLY WITH THESE EXAMPLES.

ger; for flue sheets, extend weld to one row of stay bolts lower.

When cutting out sheets or patches with cutting torch, cut them straight and bevel afterwards—preferably with a chisel. Clean surfaces are essential to good welding. Scale, rust, oil or grease must not be allowed to remain on the part to be welded, otherwise satisfactory welds are impossible. The most satisfactory angle for bevelling plates is an angle of 45 deg., making between the two plates an angle of 90 deg., or a right angle. All sheets and patches must fit with an opening of from ⅛ in. to 3-16 in. between patch and sheet all around—never less than ⅛ in. and never more than 3-16 in.

The welding of cracks in side sheets, door sheets, fire doors, crown sheets, bottom and top of flue sheets should not be attempted, or only resorted to in cases of extreme emergency, to be corrected at the very first opportunity. Welding cracks in barrel of boiler, welding over stay bolts and welding stay bolts is not allowed under any circumstances.

Welding of Full-Welded Fireboxes

A full-welded firebox is one which has all of its joints welded instead of riveted. The welded joint, to the investigator's opinion, is stronger, more economical, will not leak, and has more durable expansion and contraction properties than the riveted seam. The welding should be performed as follows:

First place the firebox upon the mudring A B A B, Fig. 1, and bolt it fast. Next, prepare to weld the outside, or water side, of say the flanged flue sheet to the firebox, as shown at Fig. 2, by cutting a bevel of about 45 degrees all the way along its edge from mudring to mudring. Now bevel the matched edge of the firebox in like manner. The best practice is to make the flange of the flue and door sheets so as to include a row of radial staybolts. See Fig. 4.

After this set the firebox so that the weld joint remains open at its bottom about 3-16 in., Fig. 3, allow for expansion, to clinch the welding metal and insure a perfect weld through the vee. Start the joint by welding it for about an inch just above the mudring, say at 1, Fig. 1, using 3-16 in. or ¼ in. Swedish iron welding rod, and a good welding blowpipe with suitable tip. From a point about 10 in. up from the mudring weld downward from 2 to 1. Then, continuing the method, weld from 3 to 2, from 4 to 3, and so on. This practice will prevent the spreading of the joint from unequal expansion. Add enough welding rod to raise the surface of the weld about ⅛ in. above the original metal. If practicable, a second welder should follow the outside welder and smooth-flow the joint on the inside while it is red hot. This will be certain to make the joint tight.

Working from the inside, weld the firebox to the mudring at the corners A and B, Fig. 1, then weld on the door sheet the same as the flue sheet.

Welding Semi-Welded Fireboxes

A semi-welded firebox is one on which welding is substituted for riveting along the lower vertical joints of the flue and door sheet with the side sheets. This practice is followed where it is desired to avoid riveted joints in the fire zone, and some shops also weld the bottom horizontal joint of the firebox and the mudring for about 12 inches both ways from each corner. The chief advantage of this welding is the elimination of leakage. The work should be done as follows:

First bolt the firebox to the mudring and rivet the flue and door sheets to the side sheets down to within about 36 inches from the mudring. Omit the rivet holes along the corner joints to be welded from 1 to A, see Fig. 5. Also leave out temporarily the rivets next to the top of the joint at 1, Fig. 5.

PREPARING WORK

To secure a successful weld, you must first prepare the work properly. There are five important things to observe, viz., the cleanliness of the sheets at the welding seam, that the sheets are bevelled at proper angle, that they are in correct position, that provision is made for expansion and contraction, and that you have suitable welding rods for filling material.

Next prepare the side sheets as shown in Figs. 6 and 9, but cutting into the flange about ⅝ in. so that it can be set down flush. Butt the joints and bevel both edges at about 45 degrees on the outside of the firebox. Leave a 3-16 in. opening at the bottom of the vee as shown. Some welders have used a lap weld like that shown at Fig. 7, but it does not make as strong and tight a joint. The butt weld as shown at Fig. 8 is the best for such work.

The next step is to tack-weld the flange at 1, see Fig. 5. Use a good welding blow-pipe for this purpose, making sure you have a suitable tip, and a good grade of welding rod.

Starting on the outside at about 10 inches below 1, weld from 2 to 1. Then from 3 to 2, and 4 to 3. Complete the joint by welding on the inside from A to 4. Weld the other three corners in like manner. If a second welder is available the metal should be flowed on the inside while being made.

Welding of Semi-Welded Half Side Sheets

Semi-welded half side sheets are those which are welded along the horizontal joints to the crown sheets, and are riveted to the mudring at the bottom and to the door and flue sheets at the ends. The welding of the long seams should proceed as follows where the door and flue sheets have not yet been set.

First proceed to bevel the edge of the half side sheets and the corresponding edge of the crown sheet as shown at Fig. 10. Next screw in the second row of staybolts and bolt the sheet to the mudring before starting to weld. To avoid delay, all of the staybolts, except the rows adjacent to the weld may be screwed in and set, and the side sheets riveted to the mudring before the welding is done.

On this being completed, weld about 2 inches of the joint at 1, Fig. 11, then, beginning at 2, about 10 inches from 1, weld back to 1, from 3 to 2, and so on to the end of the joint. Use a good welding blowpipe, with suitable tip, and as before, make sure a good grade of welding rod is used. The door and flue sheets should now be riveted in.

If the side sheets are to be put in after the door and flue sheets have been set, the flanges of the door and flue sheet should be heated and raised as shown at Fig. 12. This will allow the part of the joint under the flange to be bevelled.

When the new door and flue sheets are put on, the adjacent rivets A, see Fig. 12, should be left out until the welding is completed.

In Fig. 13 is shown the practice of welding the end of the long seam when it is desired to change an old riveted joint to a welded one. The vertical weld should be carried to the second rivet each way.

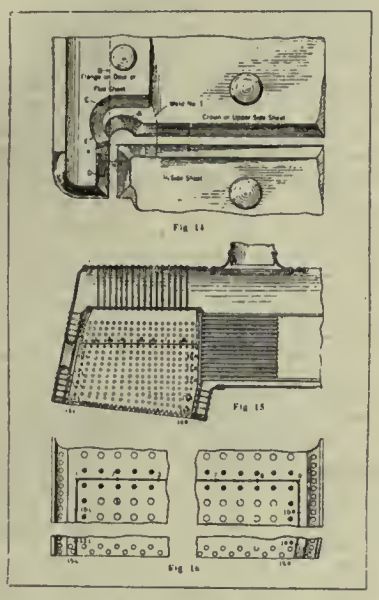
Full-Welded Half Side Sheet

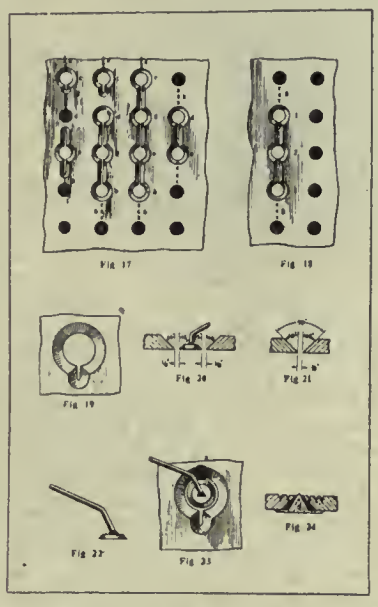
A full-welded half side sheet has no riveted joints at the top or sides, all three edges being welded. The work should be performed as follows: Cut out the flange of the door or flue sheet next to the joint of the crown and half side sheets, as shown at A and D, Fig. 14. Then bevel the flange, including rivet hole C, and set it flush with the half side sheet. Next bevel the crown sheet, including the rivet hole B. Now set the side sheet so that a ¼ in. space is left at its top and sides, and then bevel those edges. If this sheet is not riveted to the mudring, bolt it fast. Screw in and set all staybolts except those next to the welds.

Now weld the horizontal seam for about 1 in. at 1, as shown at Fig. 15. Then from point 2, about 10 in. from 1, weld back to 1, and from 3 to 2, continuing until the joint is completed. Next start about 10 inches down the vertical joint of, say, the door sheet at 10L and weld up to 1, see Fig. 15. Then from

10 inches below 10L and 11L weld back to 10L, from 12L to 11L, and so on to within a few inches of the mudring.

Weld the flue sheet joint the same way as the door sheet, from 10R to 9, see Fig. 15, from 11R to 10R down nearly to the mudring. Weld the bottom of the joints to the mudring at 15L and 15R last. When the flanged joints of the door and flue sheets are in good condition, but the rest of the plate needs renewing, a good job may be performed by setting in the half side sheet, as shown in Fig. 16. It should be tacked at 1. Then weld from 2 to 1, 3 to 2, and so on, following the practice described above.





FIGS. 14 TO 24.—FURTHER EXAMPLES. SEE TEXT FOR DESCRIPTION.

Welding Cracks In Side Sheets

Cracks in side sheets between staybolt holes are not easily welded, because of the difficulty of making proper allowances for expansion of the metal. In fact, if a side sheet has many cracks like those shown in Fig. 17 it would be better to put in a new sheet rather than resort to welding. Much welding of side sheets is being done, however, and the following method may be successfully used when the staybolt holes are to be closed:

To weld a crack like that at Fig. 18, bevel the sides of the hole and crack, as shown in Fig. 19. Prepare for each hole a soft steel disc about 3-16 in. thick and of say ¼ in. smaller diameter than the hole. Bevel the edges of the disc, as shown in Figs. 20 and 21. Melt a piece of welding rod to the disc to serve as a holder, hot-bending the rod, as shown in Fig. 22.

Next place the disc in the hole and melt down the upper edge a, see Fig. 23, to tack the disc in position. Preheat the metal between the two holes at xxxA, Fig. 18, and keep it red hot. Melt off the rod and complete the welding of the disc into the hole. Now allow the hot section xxxA to cool with the weld at 1. This provides for uniform shrinkage. Weld hole 2, Fig. 18, in the same way, and then weld the crack from 2 to 1. Preheat the section xxxB when welding the last hole of that line. The weld should be reinforced, as shown in Fig. 24.

In some cases where it is not practicable to replace a badly cracked side sheet by a new one, or put on a patch, the welding may be done as follows: Referring to Fig. 17, preheat the top of the left row of holes at xxxa. Then weld in hole c of this row. Preheat the area xxx down to d, as well as that at xB. Weld the crack at the bottom of the hole e of the first row, then the staybolt hole e, the crack at the top of this hole, and finally weld the joint around the head of the staybolt d, which is assumed to be in good condition. Reheat the area xxxa to relieve the shrinkage strains, and let the job cool down before proceeding with the other rows.

Weld the last row on the right next by preheating at xxxa, filling the holes at d and e, and then the crack between them. Reheat the lower part of the row at xxx, and allow the whole job to cool uniformly. Now weld the second row from the left in the usual way, and allow the sheet to cool again. Weld the third row from the left last, which is done in this case because it is the longest continuous crack.

MICA AND ITS USES

Mica is one of the most useful minerals, the production and distribution of which is little known. Of the many varieties, only three are of commercial importance, and of these but two are available in any quantity—the muscovite, or white mica, and the phlogopite, an amber mica. The latter is the most important of Canadian micas.

India is the largest producer of mica, providing over 50 per cent. of the world's supply. Canada produces about 25 per cent., and the United States and other countries the remainder.

In Canada, mica occurs pretty generally. The most productive areas are situated along the lower St. Lawrence below Quebec, north of the Ottawa near Mattawa, and in the townships of Burgess in Leeds county, Lanark in Lanark county, and Loughborough in Frontenac county, also in a few areas in British Columbia. The production of 1919 was valued at $273,305.

Mica mining is attended with many difficulties. For successful exploitation it is essential that the miners be experienced in the mining of this material, and be familiar with the special conditions and problems it presents. Many good mica deposits have been abandoned on account of the lack of experience of the operators.

The general run of mine mica is of a small size. A very small percentage produces sheets of 4 x 6-inch surface, while fully 50 per cent. will cut to 1 x 3 inch sheets only. Fortunately, a process of cementing the small sheets enables the building up of larger surfaces. This product is known as "micanite" or "mica board" and is mostly used in the electrical industry for insulation. Mica is largely used in the manufacture of boiler and steam pipe covering, its insulating properties exceeding by far that of any other known substance. Comparative tests have demonstrated that the loss of heat from bare pipes has been reduced by 90 per cent. when the pipes were enclosed in mica covering.

Owing to its resistance to shock, mica is used for spectacles or goggles worn by workmen in industries where flying chips or sparks endanger the eyes, and in observing processes of melting and fusing in furnaces. The small pieces of mica, formerly wasted, are now used for various purposes. When ground fine in oil, mica forms a valuable lubricant, especially for shafting or journal boxes on locomotives or railway cars. Ground mica, when mixed with a flux, is also used in giving to wallpaper and other substances a silvery effect.

So many uses are being found for mica that what was formerly an industry with a very large proportion of waste is now one in which the material is almost completely utilized.

W. Stuart Cooper, a commercial traveller with a wide knowledge of trade conditions in the West Indies, is now in Canada for the purpose of further developing trade between the two countries. Mr. Cooper intimated that trade conditions in the islands are steadily improving, and emphasized the fact that an increasing desire for Canadian trade is evident. Mr. Cooper has established his headquarters in Montreal, with offices at 401-403 Sun Life Building.

DEVELOPMENTS IN SHOP EQUIPMENT

RADIAL DRILL

The Niles-Bement-Pond Co., with general offices at 111 Broadway, New York, have placed on the market a new line of radial drills, which are termed right line radial drills.

These machines embody many radical changes, and the drive has been greatly simplified so that a higher percentage of the horsepower is delivered to the spindle. The design also gives increased rigidity, greater convenience of operation, and wider adaptability.

The feature that is perhaps the most decided departure and that adds to the rigidity of machine and simplicity of the drive is the patented double column. The design of this column is clearly noted from the illustration accompanying the article.

The column is a single casting formed of two box section members cast integral at the top and bottom, the arm saddle being mounted between them. This construction permits the simplest and most direct drive from the motor to the spindle. The motor is mounted on the back of the arm saddle and drives the spindle through a single horizontal shaft running between the column members, two-thirds of the usual driving gears and shafts being eliminated.

Column of Beam Section

Since the column is not of the stationary type but rotates with the arm, it has been possible to place the metal to the best advantage in the form of a patented beam section which is much stiffer than a circular section of the same weight. Furthermore, the bending stresses in the column are always in the direction for which its section is designed. In order to give additional support to the column, the trunnion or circular part extends through to the bottom of the base.

Another advantage of this type of column is that it permits the use of V-type tracks at the front and back for guiding the arm saddle. When clamped by means of a wedge action on these tracks, the arm and column form a rigid unit. The column can be instantly clamped rigidly to the pedestal by means of a motor operated device. Its simplicity and convenience are shown in the illustrations. The operator need not leave his working position at the drill, as the clamp is engaged and disengaged by simply throwing a switch located on the drill head. A lever for clamping by hand is also provided.

The clamping mechanism consists of a hinged conical ring acting on the column trunnion. When the ring is contracted by hand or power, it pulls the column flange down firmly to the pedestal.

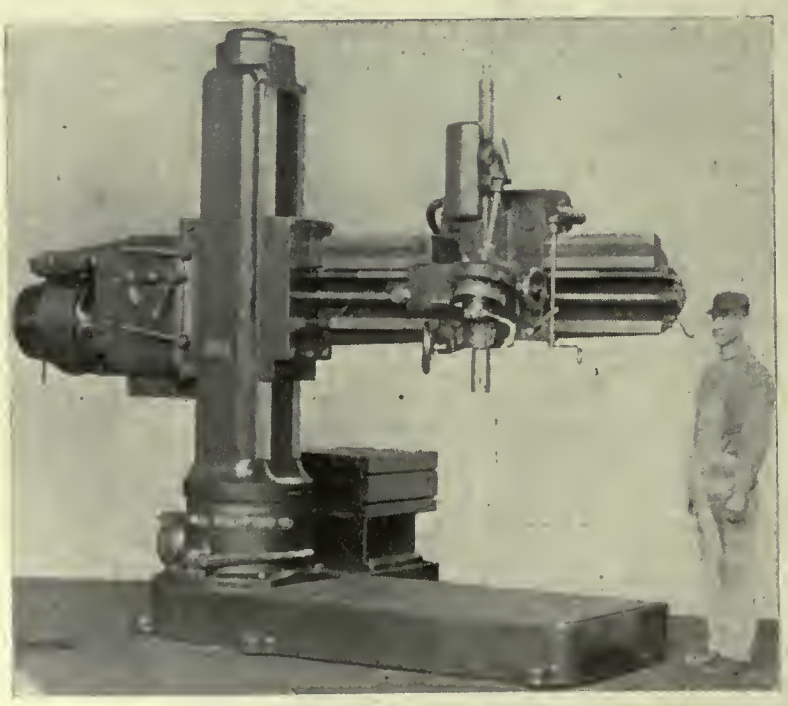
The electric clamp is operated by a small motor through worm-wheel and nut. The mechanism is self-adjusting, wear being taken up automatically. As this clamp is operated by electricity instead of air, it uses the same source of power as the driving motor. Therefore, when installing these machines, no consideration need be given to a compressed air supply.

The arm is especially easy to swing, the entire weight of the arm and column being supported on a ball bearing at the bottom of the column, in addition to which any side thrust is taken on two roller bearings. When the clamping mechanism is relieved, special springs lift the column a few thousandths of an inch so that the column flange clears the pedestal. Friction at this joint is thus eliminated and the arm and column turn entirely on the ball and roller bearings.

The arm is of a new patented section and is especially designed to give greater resistance to the drilling pressure. The most important features are an upper narrow guide for the saddle and the lower bearing set in a plane back of the front surface. This construction brings the driving shaft closer to the spindle and gives a greater depth from the front to the back of the arm; therefore, for a given amount of metal, the arm is much stiffer than arms of the usual designs.

The arm is raised and lowered by power from the driving motor operating through the stationary elevating screw and a revolving nut in the arm saddle. The mechanism is engaged by throwing the clutch lever located on the driving gear box and is started and stopped by the controller handle on the drill head. The elevating and clamping mechanisms are interlocking so that the elevating mechanism cannot be engaged until the clamp is relieved nor can the arm be clamped until the elevating mechanism is disengaged.

Another valuable feature on these machines is the automatic stop to prevent accident or damage to the machine, should the operator carelessly run the arm to the limit of its travel at either the top or bottom. This device also stops the arm in case the arm or spindle strikes an obstruction in lowering.



GENERAL VIEW OF THE DRILL.

The elevating screw is hung at the top of the column on a friction ring. When the arm reaches the top or bottom of its travel, the revolving nut comes in contact with a pin on the screw causing the screw to turn and thus bringing the arm to a stop. When the spindle or arm meets an obstruction in lowering the elevating screw is lifted and turns freely, thus stopping the arm.

Spindle Drive

The most important advantage of the double column construction is that it makes possible a drive so simple and direct that there are only four gears and one double-faced pinion from the motor to the spindle. The power is transmitted direct to the spindle by a horizontal shaft running through the column and is applied at the lower end of the spindle, as close as possible to the drill.

The gears for direct drive consist of two spur gears at the motor end and two bevel gears and an intermediate double-faced pinion in the drill head. The back gears are located in the gear case next to the motor and run in oil.

The motor controller is located on the head and the spindle is started, stopped, reversed or varied in speed by a convenient lever.

The spindle counterweight is geared directly to the spindle and is supported at its centre of gravity to eliminate friction and binding on the guides.

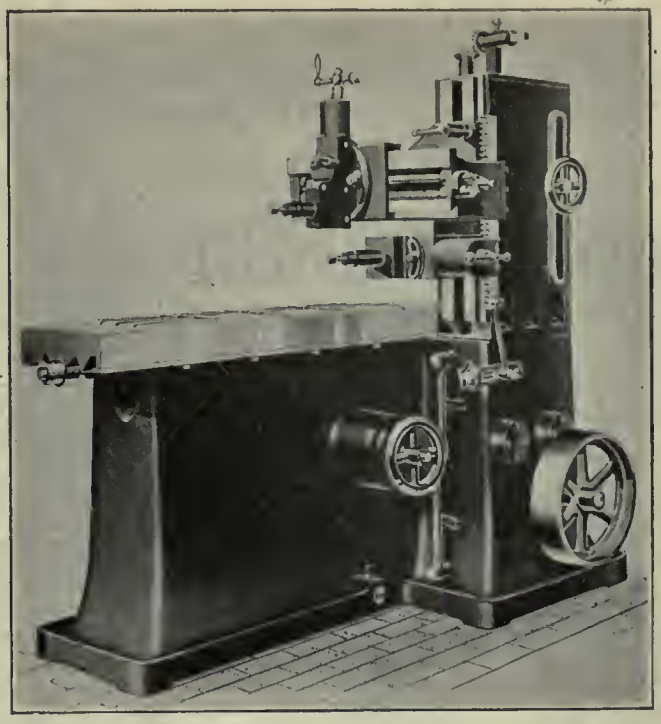
The range of the feeds and speeds is sufficient to take care of any boring ordinarily required of a radial drill, in addition to drilling and tapping. There are eight positive geared feeds which are changed by means of a disc, graduated to show the feed for each position. The feed change gears are entirely enclosed and run in oil. They are so constructed that they can be taken out of the head as a unit.

UNIVERSAL SHAPER

The Universal Machine & Tool Co., Canton, Ohio, have placed on the market what is known as their 24-inch Universal Shaper. This machine combines various features well worth describing.

The machine is claimed to fill the gap between the shaper and planer, and is said to be able to handle work of awkward shape. The ram stroke has been replaced by a speedy table stroke, and the natural lifting tendency of the ram is replaced by the action of the universal table, giving as high as 40 strokes per minute.

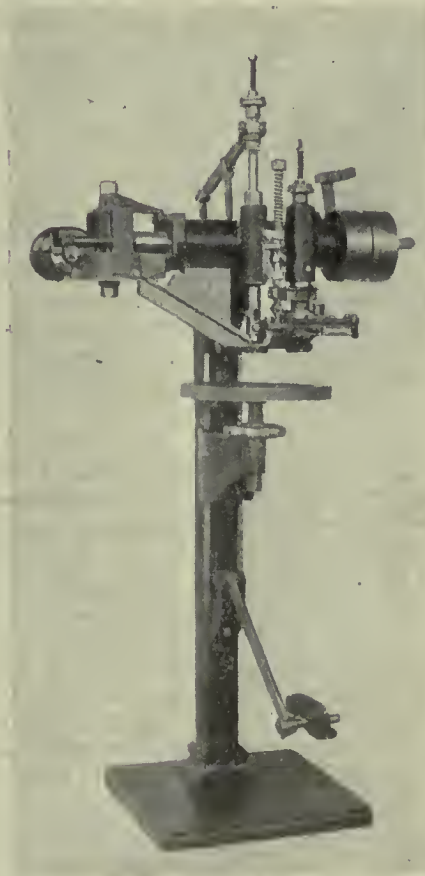
Four speeds are controlled by two levers on the operator's side of the machine, these giving speeds of 7. 20, 30 and 40 strokes per minute. All operating levers are placed on the operator's side, and with the open side feature it is possible to clamp long work to the table without obstructing the operator. The machine is of rugged design and is said to be capable of taking an extremely heavy cut. It is single belt driven, has power feed to head and saddle, and all shafts run in ball bearings.



GENERAL VIEW OF THE SHAPER.

SCREW DRIVING MACHINE

The Reynolds Machine Co., Massillon, Ohio, have developed a machine that sets and drives small screws in place, thus speeding up light assembly work. Some of the applications to which this machine is suited are in driving electrical binding screws, switch box screws, washer head screws, etc.



GENERAL VIEW OF THE SCREW DRIVING MACHINE.

This concern has hitherto built machines which automatically feed and drive screws of ordinary proportions, but this new machine handles screws having a length less than the diameter of the head.

In operation, screws are thrown at random into the magazine at the right of the machine. This magazine automatically arranges them in single file with heads upward and delivers them in this position into the inclined track shown leading from the magazine. Opposite, and closing the lower end of the track is a finger recessed to receive one screw and hold it in line with the spindle. The spindle, which carries a screw driver bit, is brought down by the foot lever, the bit engages slot in screw head and finger and screw are carried downward until the point of screw engages work, when the finger is automatically withdrawn to allow the screw to be driven home.

The spindle is adjustable frictionally driven so that screw driver bit stops when screws are driven as tight as desired, or screws can be merely started, or driven to a uniform depth. Table is twelve inches in diameter and is adjustable on column to take up to fifteen inches high and has screw for close adjustment. Foot lever is pivoted well above the pedal to give an easy swinging position, and can be adjusted both for position and resistance to suit convenience of the operator. Operation of machine with foot lever leaves both hands of operator free to handle or assemble work. Spindle may be run several hundred R.P.M., setting screws practically instantly, and the machine is driven with tight and loose pulleys as shown, or with individual motor.

A Good Time To Buy Tools

RIGHT now is a good time to buy in the machine tool market. That may be a peculiar remark, but it is a fact.

You can get service now that you could not possibly get six months ago, and which you may not be able to get six months from now.

Many of the larger makers announce that they will protect buyers in the matter of price decline, so there is nothing to be afraid of in this respect.

Buyers should take advantage of the fact that it is a buyers' market now. They accuse the sellers of taking advantage of the situation when the tables turn and the market becomes one that is dominated by the sellers. Why, then, would it not be good business for a buyer, when a buyers' market turns up, to go in and make the very best bargain he can? He certainly can talk with greater freedom now than he could a year ago. The situation is here and it is all in his favor.

It may be that we are facing another situation like the one that followed the close of the war. Every person stopped still for a few weeks. There was no particular reason for it, but it happened just the same.

Right now we are in a similar place. People are stopping. There is no good reason for it. We have not had a crop failure—we have not had a panic, neither are we facing another war.

It all seems to be because our dollar is growing bigger when we come to spend it. It is worth more now than it was three months ago when we take it out into the markets and exchange it for the things we need.

If you are a prospective buyer right now should be a good time to go in and talk to the machine tool dealers about your requirements. You will find that they have time to talk to you, and give you good attention. You may find that you can buy to advantage. It is worth trying. We are not going to stay where we are for very long and the first thing you know it will be turning around again to a sellers' market and you will have to take what you can get and stand in line for some months to secure it.

Picking War Plants To Pieces

RUNNING stories of how United States wasted money in the war is getting to be a favorite subject with a good many papers.

For instance, investigation shows that the Government let 111 contracts to the amount of $478,828,334 for the construction of artillery of all calibres, guns, howitzers, gun carriages, limbers and recuperators. Of this immense programme of expenditure there reached the American troops and were actually used in combat 39 75-millimeter anti-aircraft mount trucks, 48 4.7-inch guns of the 1906 model, 48 4.7-inch gun carriages of the same model, 24 8-inch howitzers and 24 8-inch gun carriages.

Then for the turning out of explosives the expenditure ran into the millions, while the explosives ran into nothing at all. In fact, the amount of explosives and gas from the United States war shops that ever reached the front was very, very small.

It might be possible to go ahead and deliberate upon this waste and extravagance at great length, but look at the other side. Take a few of the cases right around here. It might be possible to go up to the splendid Leaside plant in the latter days of the munitions manufacturing when they were getting tuned up to turn out the 12-inch shell, and say "Look at all this plant here, fine machine tool equipment, great shops and layout. All this and no production."

Again it might be possible to go to Motor Trucks at Brantford, when a large building for this purpose was put up at an abnormally high cost, and look at that place. There it was, hundreds of thousands of dollars' worth of equipment being rushed in there and put in position, work going on at feverish haste in order to get that one thing most necessary—production. Did they get any? No, they did not. As far as we know that great plant never turned out a cent's worth of shells.

Well, it would be a very simple matter to go to that plant and say, "Look at that for waste. A great steel structure in the first place. All rigged up with the best of equipment, all heated, power transmission machinery there. A big organization and yet not a cent's worth of output to be put over against all that expenditure." And that charge would be perfectly true. And yet it would be just as unfair as it is true.

No doubt much of the dust that is being kicked up in United States could be traced to the same source.

In this country firms were not sorry that they lost their production. Any such feelings were swallowed up in the joy at the war coming to a close.

War is a waster, and the waste is not confined to operations at the front, nor to the districts in which battles are fought. War plants were largely wasted afterward. They were not put up for commercial pursuits, neither were they erected with the idea of competing with any other plant afterward. They were rushed up for a purpose, regardless of expense, which was in many cases very high when compared to days when things were done on a competitive basis.

It is hardly a fair thing to put a peace-time analysis to things that were done in the feverish haste that characterized much of the war work.

Chas. M. Schwab, Optimist, States His Views

CHARLES M. SCHWAB, speaking in New York a few days ago, gave some plain talk to those who are afraid of the present situation. To quote Mr. Schwab's own words in this matter:—

"But I want to go on record here as saying that nothing could be healthier for American business than the very condition through which we are now passing. It had to come. I only wish it had come sooner. The severer the storm is now, the quicker it will be over and the sooner we can emerge into clear weather and shape our course upon the sea of prosperity.

"Business in the United States ever since the war started had been, until very recently, upon a false basis. The disposition of many manufacturers had been to say not: 'Let me see your costs sheet,' but 'Let me see your statement of profits.'

"Now the true test of success in business is not profits, but economy. Profits may be the result of good fortune, of a fleeting period of inflation, of temporary conditions of any kind, but a business structure which is built simply upon the profit sheet of the moment is built upon the sands. The only business foundations which are sure and steady are erected upon the rock of economy.

"The result of this experience through which we have passed is that our costs have been inflated and we have had in America both our business institutions and American individuals generally indulging in wasteful and extravagant methods.

"The supreme virtue of the existing situation is that it is compelling every business man in America, in fact, every individual in America, to examine thoroughly his costs of doing business and his costs of living. The result of it all is to force business and to force individuals to start to economize and to save.

"I hear men say that the greatest need of the hour is the liquidation of labor. In saying this many have in mind the high wages now being paid to labor and industry, and mean that labor must adjust itself to a new standard of living.

"Now the laboring man is primarily interested not in the amount of money paid to him, but what his money will buy. If the cost of living comes down there is no question that our American laboring man can maintain his present standard of living even though his wages as stated in dollars amount to a lesser sum than before.

* * *

"In the steel industry one-half the total cost of making steel is the cost of labor. You can, therefore, see how important efficiency and labor costs are in all items of manufacture.

"The laboring man is entitled to his full share for the contribution he makes to the value of an article. The laboring man should be taken into the fullest confidence of his employers. He should be so sure of getting his fair share of the wealth he produces that he will work with zeal and enthusiasm.

* * *

"The world during the past few years has been a spendthrift and a waster. It has spent its life and its blood in prodigal living. It has spent a large part of its liquid wealth and has now come to a period where it can go forward only by energy and effort of the most vigorous kind.

"When, therefore, our business men thoroughly study and cope with these problems of economy and make up their minds to go ahead and to produce to the utmost on a smaller margin of profit than they have been accustomed to realize in the years of inflation, then our course will have been set toward a haven of safety and progress.

* * *

"At the moment, our export trade hangs by a slender thread. The exchanges have been moving altogether too much in our favor. We are rapidly getting into the position where the whole world owes us money and yet cannot pay it. We have recently seen a little cloud on the horizon out in North Dakota. Certain farmers owed the bankers money. The value of the produce which secured the loans went down below the value of the principal. The bankers called the loans and the farmers could not pay. This process has resulted in closing something like twenty small banks in North Dakota during the past few weeks.

"The whole world owes the United States money and the whole world is hungry for the things the United States can supply. Not quite a year ago, one of our great financiers returned from Europe and suggested that we create a revolving fund of $500,000,000 to finance the absolute requirements of Europe and start the countries in distress on their way to self support. Perhaps he did not state the correct sum, but for lack of our ability to sell to Europe through having sufficient credit available, the value of the farm products of this country, which Europe would like to buy, has decreased during the past few months not hundreds of millions, but billions of dollars.

"If the business of the United States is to go forward as it must go forward, our people must take a world view. We must think internationally. We must trust in the good faith and in the productive power of Europe, sending to them our raw materials and goods to enable them to resume productivity, and accepting in payment therefor securities representing their productive activities."

"Iron Age":—To sum up, certain readjustments of past periods of depression that required time for completion are not needed now, while the readjustments that are needed to-day are theoretically unending, cannot be pursued to their end because they have none, and hence will not be pursued indefinitely. We may be able to resume work, therefore, and on an intelligent and safe basis, in a shorter time than many new seem to think is probable.

Appointed General Manager

C. R. BURT, M.E., has been appointed general manager of Willys-Overland Co., Weston Road, Toronto. Mr. Burt is no stranger to this country, having been connected with the Russell Motor Co. for some years. He is a thorough mechanic, as well as a capable plant executive. Starting as a boy, he was an apprentice with Brown & Sharpe, Providence, R.I., where he remained for twelve years, being sent by that company in 1900 to Europe to study conditions and practice there.

C. R. BURT.

A few years later, he became connected with the Barber-Colman Co., at Rockford, Ill., makers of gear cutters, etc. While engaged at this plant Mr. Burt designed and perfected the Barber-Colman gear hobbing machine.

It was in 1913 that Mr. Burt came to Canada as factory manager of the Russell Motor Co., and the following year he was appointed assistant general manager and given a place on the board of directors. In this year he made another trip to Europe for the Russell Co., to look into conditions of trade and motor car practice in general.

Shortly after this the munitions contracts started to come to this country and Mr. Burt had much to do with the successful operation of the big munitions plant put up and operated by the Russell Motor Company.

MARKET DEVELOPMENTS

Some Bright Spots Seen In The Dull Market

Dealers Report Some Good Orders, but Markets are Mostly Quiet With Little Trading—Independents May Move to Cut In on the Corporation Prices if They Can Get Business

A FEW nice orders were secured in the machine tool market during the week and these provide the bright spots. Otherwise trade was not up to the mark. Several of the principal makers have notified their agents that they will protect buyers against price declines for the coming six months. Buyers do not seem to be taking advantage of the fact that it is a buyers' market now, and they could probably come in with their requirements to much better advantage than at any time during the past three or four years.

Local warehouses have announced new prices on some lines. Bar iron and bar steel are selling at 5c base. Sheets and plates were also put on a lower level. There is a fairly large stock of sheets in store, quite enough to take care of the present requirements of the trade. Manufacturers still send out lists of surplus material on hand, and the peculiar situation is found at times of the dealer trying to sell the manufacturer the very materials that the manufacturer would like to see the former taking off his hands for resale.

One of the largest dealers in scrap metals notified some 3,000 firms during the week that for the present they were entirely out of the market as far as taking on anything in the line of brass, copper, zinc, lead, spelter, etc., is concerned. In fact they are out of the whole non-ferrous line, and in iron and steel they are buying only against contracts. This is the first time in the history of their business that they have sent out such notices. They intend to keep out until something definite is established as a working base in the metal market. During the past month they have had to write off some hundreds of thousands by way of depreciation on stock in their yards and warehouses.

BRIGHT SPOTS SHOW UP IN THE WEEK'S BUSINESS IN MONTREAL

Special to CANADIAN MACHINERY.

MONTREAL, Dec. 16.—The varying reports of fairly good trade and dullness from dealers and agents, makes it difficult to state, definitely, what the actual market conditions are at the present time. Intermingled with the usual statement that business is more than seasonably quiet, one is confronted now and then with the information that activity is even above normal. One steel and heavy hardware firm here, during the past week, has had exceptionally good business of late, and reports that the present period compares very favorably with corresponding weeks of previous years, barring the abnormal demand during the years of the war. However, business in general is comparatively quiet, but in the opinion of many is more the result of bank regulations than that of actual trade requirements. Business today is temporarily diverted to retail activity, and for the next two or three weeks will overshadow other lines of endeavor, but with the turn of the year the prospects appear good for a gradual return of general industrial and commercial enterprise.

Waiting For The New Year

No outstanding features have developed to alter the general quiet condition of the steel market. There is little doubt that American mills are doing their best to induce buyers to come into the market owing to the depleted condition of the mills' order books, but the recent declines have, as yet, failed in doing this to any great extent. The existing demand is not such as would call for any keen competition, for if it was so, it is thought that prices would show a more rapid decline. Local trade shows no change from that of last week, the movement being light but fairly regular. It is anticipated that price quotations here will be revised about the beginning of the year, when it is expected that activity will show a gradual, though perhaps slow return to that of several months ago. Plate movement has eased up a little, and likewise sheets, although galvanized lines are none too plentiful.

Anticipating Good Business

While few dealers are denying the slackness of trade and the hard efforts that are necessarily required in obtaining sufficient orders to keep things going to the extent of "just paying the way," the majority of the tool dealers in this district have a cheerful note to sound when speaking of next year's business. There may be nothing of a tangible nature to warrant this attitude, apart from the fact that the needs of industry, in the way of increased equipment or replacements, while apparently adequate for a curtailment period through which we are now passing, are nevertheless insufficient to maintain even normal operations, should trade suddenly return to former activity. Dealers report fairly good business in the lighter supplies but admit a slight falling off from previous weeks. Some little business has been done in used equipment but sales of new machinery, particularly of the heavy variety, are few and far between.

No Interest In Scrap

Dealers are almost indifferent to the present situation, fully believing that

nothing of a special character will develop this month to change the market from the listlessness through which it is now passing. Price, apparently, is not the obstacle that must be surmounted, as any reduction in scrap quotations fails to bring other than casual inquiries. As long as retrenchments are the order of the day, with industrial production being curtailed in many quarters, the consumption of scrap is reduced to a minimum, and consumers will not buy more than they actually need to carry them over the immediate present. At the same time dealers are not anxious to accumulate yard supplies, so that the result is one where inactivity is the dominating feature. Some of the steel scraps have been reduced. Boiler plate, heavy melting steel, malleable scrap, and stove plate, show a decline of $2 per ton. Wrought iron pipe has declined from $9 to $8.50 per ton.

SOME GOOD SALES ARE BEING MADE

But in the Main the Machine Tool, Iron and Steel Market Continues Quiet

TORONTO.—It would be wrong to get the idea that there is no business in the machine tool market. There is a certain amount of selling, and the tools being sold are good sized ones, involving in several cases a pretty fair sale price. Dealers say that buyers are not asking much about the prices. Several of the larger firms have gone this far—they are protecting their buyers in the matter of price for the ensuing six months—that is, if in that period the price is put to a lower figure than that paid by the purchaser, he is entitled to a rebate of the difference.

One of the dealers seen this morning has just returned from a trip to several of the centres, and he is of the opinion that there is not going to be a return to pre-war prices, but that the values will find their new levels fairly well above the old prices. "There were firms in the machine tool business that never made enough out of it to grow as they should. I can think of several that have always turned out a good product, and almost at any time they have been ready to throw up their hands and quit because they never made enough to see them through rough spots. Not only that, but there is a pretty well fixed belief that the cutting of prices would not bring any more purchasers into the market. We are quite satisfied to go ahead and sell on the present lists, feeling that we are getting just as much business as though we had a new and considerably revised schedule."

Although nothing definite has been announced it is felt that the automobile firms will be getting under way, probably on a small basis at first, around the beginning of the year, and they are looked upon as likely to have some pretty fair inquiries to attend to. Taken as a whole, the machine tool business is quiet, but there are bright spots, and the trade in general is not in a mood where it is complaining.

Steel Market Easier

Several prices were marked down at local warehouses this morning. Steel and iron bars are now selling at $5 base. Steel plate is quoted in most cases at 6c. Sheets are to be had for 9 cents for 28 and 7.50 for No. 10. Galvanized is selling around 11.50, and is none too secure at that figure.

Very few of the warehouses are taking in sheets now. In some cases they claim to be well enough stocked to run along now for three months. Fortunately prices are mixed enough to enable most of them to keep pace with the decline in prices. There are still some sheets in stocks that were taken in at high prices, and these, put in with shipments of lower priced goods, makes the present price. There are still a number of manufacturers who have a certain amount of surplus material which they are trying to unload. In fact there have been cases where a dealer was trying to sell the same line to a manufacturer that the latter was thinking of trying to sell to the dealer. There is not sufficient quantity of this in the market to make any serious difference in prices. The market seems to be pretty well filled with sheets for present requirements.

Tubes are fairly active, and there is a good assortment in several of the warehouses. Bar mill products are not moving very rapidly.

Preparations are being made in some of the warehouses for getting in shape for renewed buying after the first of the year. Some of the dealers believe that we are passing through a period much the same as that which came shortly after the war, when there was a lull in trade for a short time, to be followed by a period of keen buying. Were such a situation to develop it would result in stiffened prices, as there are no large reserves.

Out of the Market.

There is nothing in the scrap metal trade to indicate that dealers are looking for a revival before long. One of the largest yards stated to Canadian Machinery: "We are sending out notices to over 3,000 firms that we deal with stating that until further notice we will not take on any non-ferrous metals under any consideration. We cannot see our way clear to keep in the market at any price until something happens to settle the schedules for dealing and give us some reason for believing that we are down to the bottom in the matter of prices. It looked for a short time at the start of the week that the market was going to gain strength, but just at the moment when this looked possible both New York and London went weak,

POINTS IN WEEK'S MARKETING NOTES

Steel ingot production in United States for November was 15 per cent. less than in any of the corresponding three months.

—

Independent steel mills are shortage of business, several of them operating at the present time at not more than 60 to 70 per cent. It is generally conceded that it does not pay to run a mill much under 70 per cent. of its capacity.

—

Pittsburg believes that the next market development will be cutting of Corporation prices by some of the Independents. The big question is whether such practice would bring them any business.

—

The production and sale of pig iron is in smaller quantities than for some time past. Foundry iron is quoted at several places at $33 and $35.

—

Several machine tool firms are announcing that they are willing to protect buyers against price reduction for a period of six months.

—

Some very nice orders have been secured during the week by machine tool firms, although on the whole business is still quiet.

—

Several lines of steel were marked down in warehouses this week. Bar iron and steel are now selling at 5c base. Black sheets are quoted from warehouses at 9c.

—

There is still a good demand for boiler tubes and there is a complete range of these in stock at most of the steel merchandising warehouses.

—

The largest scrap metal dealer in this district has sent out word to some 3,000 customers that for the present his firm does not intend to buy any non-ferrous metals. They will not take these lines at any price, while dealing in iron and steel is still at a very low ebb.

—

Some of the scrap metal dealers have found it necessary to write off some hundred of thousands of dollars in the last few weeks, owing to the depreciation of stocks in their yards and sheds.

and the thing was off. This is the first time possibly in the history of this firm when we have absolutely and positively left the market in any particular lines. We are out on the non-ferrous lines until something definite is established either up or down."

"And how about the iron and steel end of it?" was asked.

"Little better, but not much. Foundries are not buying, and the steel plants are not taking on a pound. We are not cutting the prices any lower, but it would be well for you to make it very plain to your readers that the prices quoted for old material are purely nominal. We would not undertake to pay any of them unless we had some place where we were going to place the material at once."

It is understood that some of the yards have had to write off very large amounts in the past few weeks, running into a good many hundreds of thousands.

NEW YORK MARKET IS STILL VERY DULL

And a Number of Used Machines Intended for Export Are Offered At a Price

Special to CANADIAN MACHINERY.

NEW YORK, Dec. 16.—Business in machine tools is exceedingly quiet and will doubtless remain in this condition until after the first of the year. Some of the railroads and other large prospective buyers indicate that their purchases will be made after January 1, but just how early in the new year they will act is not known. It is believed in some quarters that the volume of buying which may be done by the railroads in 1921 is exaggerated. Officials of the roads point out that a good many of the contemplated purchases must be financed out of current surplus profits, and with a decline in freight movement it is not apparent that there will be any large surplus profits in the next few months even with the present high freight rates. Moreover, if money is borrowed by the railroads for such large purchases as locomotives and cars a lower money rate will be necessary. There has been a slight easing in the money rates, but not enough as yet to encourage any large borrowing.

There are varying opinions as to when a revival of machine-tool buying may be expected. Some in the trade put off the time until spring.

In the next two weeks a large number of machine-tool plants will shut down for periods ranging from a few days to two weeks. This will afford an opportunity for annual inventories and for repairs to shop equipment. In practically all plants working forces and the number of working hours have been reduced. Some companies are virtually without orders and are making a few tools for stock. However, the amount of manufacturing for stock that will be done under present high costs is apt to be exceedingly limited.

Buying of used tools is more active than the market for new machines. A considerable number of new machines is being offered for sale at concessions in prices, these machines in most instances have been bought for export. Owing to cancellations from abroad the exporters are obliged to offer the tools for sale here.

CONDITIONS IN THE BUFFALO MARKET

Steel and Iron Trade Is Down to the Level of New Quotations

Buffalo.—A further curtailment of production by blast furnaces and steel plants in this district amounting to possibly 50 per cent. of the previous scale of production is announced.

One large mill has suspended steel operations altogether.

Three out of four blast furnaces operated in connection with this interest are banked. Another large steel-making interest is operating about 50 to 60 per cent. Four out of nine blast furnaces are down and the open-hearth equipment has been partially closed. Another steel-making plant is operating about 75 per cent. This plant is operating its two blast furnaces. Two other furnaces are operating from 75 to 100 per cent.

Local mills have not published a lowered schedule conforming with present Steel Corporation and Jones & Laughlin prices, but their price policy is practically one of conformance. They state that future orders will be figured on individually, and special prices made. This policy works out to what is tantamount to the corporation schedule. One maker here has taken several orders for bars, plate and structural. The price on the bars is 2.35; shapes, 2.45, and plates, 2.65.

Pig iron sales just now are light with resale continuing to make the market. About 1,000 tons in all have been sold in the past week. This iron is being sold at various prices. Some of it is sold as low as $37; some at $38 and $40 for the base grade at foundry.

CORPORATION MILLS ARE STILL OPERATING CLOSE TO CAPACITY

Special to Canadian Machinery.

PITTSBURGH, Dec. 16.—Production of steel ingots in the United States was about 15 per cent. less in November than in either of the three months preceding, which had shown substantially the same rate. The Steel Corporation's production rate was fully maintained, while the independents had a decrease of about 28 per cent. It is possible that the Steel Corporation's output increased somewhat, and if so the independent output decreased by more than 28 per cent. The estimate of independent production is based upon the November report of the American Iron and Steel Institute. These monthly reports show the output of 30 companies, producers having 15 or 16 per cent. of the capacity not making reports. As the non-reporting producers are independents and as there is a great difference now between Steel Corporation and independent operations the report must be analysed and an allowance made for this fact. The tonnage actually reported shows a decrease of 13 per cent. for November.

The decrease in independent steel production has been continuous since the latter part of October and thus the present rate is far below the average of November. The common prediction is that by the end of this month the independents will be very largely idle, many plants closed and others operating at only 50 to 70 per cent.

The Steel Corporation's output is, if anything, increasing. The corporation has blown in several additional blast furnaces in the past few weeks, not because it did not want to operate them previously, but because it has only lately been able to secure enough coke, partly because there had been a shortage of cars in the Connellsville region and partly because the by-product plants, at the blast furnaces, could not get sufficient coal.

Steel Corporation's Orders

The unfilled obligations of the Steel Corporation at the end of November are reported at 9,021,481 tons, showing a decrease during the month of 815,371 tons, against decreases of 537,952 tons in October, 430,234 tons in September, and 313,430 tons in August. Previously, for 14 months, there had been increases.

While the November decrease in unfilled tonnage seems large, the showing is really a very favorable one to the Steel Corporation in view of general conditions. The decrease represents about 61 per cent. of capacity, but shipments were probably about 89 per cent. of capacity, and thus the net bookings were about 28 per cent. of capacity, net bookings being the difference between total bookings and the cancellations, for doubtless even the corporation had a little by way of cancellations. The average independent, on the other hand, had scarcely any bookings, while most of them had heavy cancellations, and undoubtedly many independents would show for November a loss in unfilled tonnage actually greater than the shipments.

The 9,021,481 tons of unfilled obligations at the end of November is equal to the corporation's output for over seven months at 90 per cent. of rated capacity. Of course the business would not keep the corporation operating at that rate for

seven months, since some of the business is strung out over longer periods. The corporation is, however, in a very comfortable position. The tables are turned, as compared with the time when the independents, on account of their much higher prices, were making much larger profits per ton than the corporation.

Market Stagnant.

The semi-finished and finished steel markets remain absolutely stagnant. It is probably no exaggeration to say that never has the steel market been so dull. That does not mean that consumption is at an unprecedently low ebb, by any means. The consumption is being supplied chiefly by the Steel Corporation on its old orders. The corporation has about 44 per cent. of the capacity and is shipping at the rate of about 90 per cent. of capacity. The steel shipped is doubtless all going into consumption, and there is still some production by independents.

During the period of steel scarcity there was much reference to the Steel Corporation making sales and shipments only to "regular customers." A quite erroneous view of the situation would be formed if it were assumed that the buyers of steel are divided simply into two classes, customers of the corporation and customers of the independents. A great many buyers patronize both the corporation and one or more independents. In such cases the corporation allotted steel to the customer and the customer covered his remaining requirements outside. Now, in many cases, the amount the consumer gets from the Steel Corporation is sufficient, because the requirements have decreased.

This situation must be taken into account in weighing the predictions made in most quarters that there is likely to be a mild revival of buying just after January 1. The prediction is based on the perfectly correct premise that steel consumption never ceases, that even in the poorest times in the past there has been consumption equal to 50 to 60 per cent. of capacity.. If the Steel Corporation operates full that takes care of a very large part of the "hard times demand." Then it is to be considered that the country's steel capacity has increased about 50 per cent. since 1914 and it is not yet proved that the normal consumptive demand is increased in that same proportion.

Steel Prices

As noted in previous reports, tin plates, bars, shapes, plates, wire products and sheets have come to show an independent market at the Steel Corporation level. The independent market that began about a year ago is ended. Pipe, however, remains an exception. The independents are still on their 54 per cent. list, the Steel Corporation having maintained the 57½ per cent. list of the Industrial Board. The difference is about $7 a net ton. However, some of the independents were formerly obtaining large delivery premiums, beyond their regular prices.

The common view is that the next market development will be shading of the Steel Corporation's prices by some, perhaps many, of the independents. Certainly there would be a disposition in that direction, if the operation seemed to be worth while. It is all a question of whether a mill could secure enough business by cutting prices to make an economical operation. Some of the independents used to claim that their costs were so high that they could not afford to sell at the Steel Corporation prices, but of course they included overhead in their cost. If the mill is idle the overhead is lost anyhow. On the other hand, it is not feasible to operate a mill at a very low rate, that entailing a greater rate than closing entirely. Thus, unless a mill can get enough business to operate at 60 or 70 per cent. for at least a week or two at a time it is unlikely to try to get business at all.

Pig Iron

Furnaces continue to go out of blast. There is no inquiry for pig iron and furnaces are making no effort to force sales. The foundry iron quotation has dropped from $37 to $35, valley, Bessemer and basic remaining quotable at $35 and $33 respectively.

Germany and Belgium Are After Business

Making a Strong Bid to Win Back the Connection With South Africa—Many Lines in Which Canadian Makers Might be Interested for Their Export Business are Mentioned Here.

GERMANY and Belgium are both actively engaged in their efforts for the South African trade in iron and steel, including bar iron, iron wire and tools. In barbed wire, 12 gauge, 100 pounds per gross, barbs six inches apart, the present offers from Germany are 35s 3d c.i.f. Cape Town.

In such tools as pincers, pipe wrenches, punches and other items similar to those of which German samples are shown at the Department of Trade and Commerce, Exhibits and Publicity Bureau, in Ottawa, shipments are coming in fairly freely from Germany. Occasion has been taken to see several invoices of shipments on open indents, the items on which were taken from the old 1913-14 catalogues. The several buyers interviewed point out that although open orders were placed it was only the articles which German manufacturers knew would be competitive that were shipped; in other words, no advantage was taken of the open order.

The present prices of the German tools referred to are an increase over their 1914 prices of 175 to 225 per cent.

Provided that the quality is satisfactory and the prices and terms competitive, a good business could be worked up in Australia in such lines as twist drills, reamers and milling cutters, grinding wheels, drop forged spanners, taps, dies and screwing tackle, files, vises, forges, drills, metal thread screws, and power transmission appliances; also electric house supply meters.

Australian requirements in the twist drill line are confined to carbon tools. There is a big demand for high speed tools. American prices are usually found in excess of British prices. United States manufacturers do the largest business, though Canadian houses get a portion of the trade. Business in grinding wheels is almost entirely confined to United States makers. A large and growing business is being done and the opportunity is good to participate.

The United States houses are strong competitors in the drop forged spanner business. There is an exceedingly good opening in this line but care should be taken that the right articles are supplied.

For many years traders looked to North America for their supply of files, but many merchants have turned to British supplies. There is no reason, however, why Canadian manufacturers should not obtain a share of the business. At present the largest line of taps, dies, and screwing tackle comes from the United States, which has a strong hold on the market. Canadian manufacturers, however, who will supply good tools, which are interchangeable, and of good quality, at competitive prices are assured of good business.

There is a ready sale for vises, forges and blacksmiths' drills, and Canadian manufacturers should give their attention to Australian markets.

Metal thread screws, bolts, etc., are largely used by stovemakers and motor car body builders, as well as in general engineering and standard Whitworth threads are used.

A large number of pressed steel pulleys, hangers, compression couplings, etc., are imported, but Australia makes her own wood pulleys.

There is a large demand for electric house supply meters, as great difficulty has been experienced in obtaining these for some time past.

To obtain business in any of these lines it is necessary to appoint a representative. English and United States houses are well represented, and it is almost useless for Canadian manufacturers to try and obtain business otherwise.

Developing Steel Plant

Since the Broken Hill Proprietary Co. opened its steel works at New Castle, near Sydney, Australia, in 1915, 637,213 tons of pig iron has been produced, while the output of the steel plant has been 593,223 tons. The demand for their products is so great that it has been found necessary to add to the present extensive premises. It is expected that the proposed new plant will cost £3,500,000. The extent of the company's output has enabled a number of new and important industries to spring up, the latest being for the establishment of a wire netting industry which is expected to start operations next year. When the new furnaces are running it is expected there will be an output of 450,000 tons.

The importation of agricultural machines into Czecho-Slovakia is at present prohibited, but licenses for limited quantities are granted to co-operative societies and other importers for the purchase from abroad of machines which are needed and cannot be produced in Czecho-Slovakia. The rate of exchange is a great obstacle, so that if importations were unrestricted the turnover would not be large as the price to the farmer would come high.

Another Market Here

Bohemia, Moravia and Silesia before the war offered a market for certain lines of machines and industrial equipment, such as spinning machines and other textile machines, paper, machinery, etc. There is a considerable manufacture of machinery in Czech-Slovakia and the present policy of the government permits only the purchase of machines from abroad which cannot possibly be obtained in the country. Import licenses for textile machinery from Great Britain has been refused, but certain special machines have been admitted. When the industries of the country are on a more normal and independent basis it may be expected that the trade restrictions will be modified.

Grain harvesting machines are manufactured to some extent in Czecho-Slovakia, but not so as to preclude the necessity for importation. The United States and Canada formerly supplied the bulk of mowers, reapers and binders, and importers are again looking to these countries for supplies. The low exchange value of the crown and import restrictions hinders business at present, but on the other hand, there is a lack of these implements and also a lack of agricultural labor and importations from abroad will soon be necessary. Canadian firms should now prepare the ground for future business by getting in touch with importers and co-operative agricultural societies.

Tractors and motor ploughs are another line of agricultural machinery which offers openings for future trade from abroad, home production does not cover the demand.

Prague is the most important centre for the trade in agricultural machinery and implements, while as a distributing point for Slovakia the town of Bratislava (Pressburg) also promises to be important in the future.

SCRAP METAL MARKET

The prices on the scrap metal market still continue to lower. The consumers continue out of the market.

The outstanding feature of the situation in scrap iron on the Chicago market is the increasing tonnage being offered by railroads which may be partly due to the wild weather, which makes it possible to gather and sort this material at a season when the cold and snow usually prevents it.

Sharp reductions are the outstanding feature in cast scrap and iron car wheels on the New York market. Iron car wheels have been sold as low as $24 f. o. b. New York and heavy machinery cast at $25 and $26 respectively. This is a reduction of $5 to $6 and in the other grades of $3 and $4 respectively.

The business on the Philadelphia market is confined mostly to forced sales and trading among dealers. The continued absence of buying is bringing further drops in scrap prices. Heavy melting steel has been bought by dealers at as low as $15.50 delivered.

Planning Tooling and Operations for Lever

The Lever Under Discussion Is For Use on a Standard Milling Machine—Five Operations Are Entailed, the Only Equipment Used Being a Lathe, Milling Machine and Drill Press.

By E. N. DAVEY

AN important feature in designing the tools and operations for this piece, to my mind, is the equipment of the shop. For my purpose let us suppose it is to be made with an ordinary engine lathe, milling machine, and drill. If a turret lathe and multiple spindle drill are to be used the same equipment can be modified to suit, and would naturally cut the price of production a little. I think this piece could be best handled in five operations, namely.

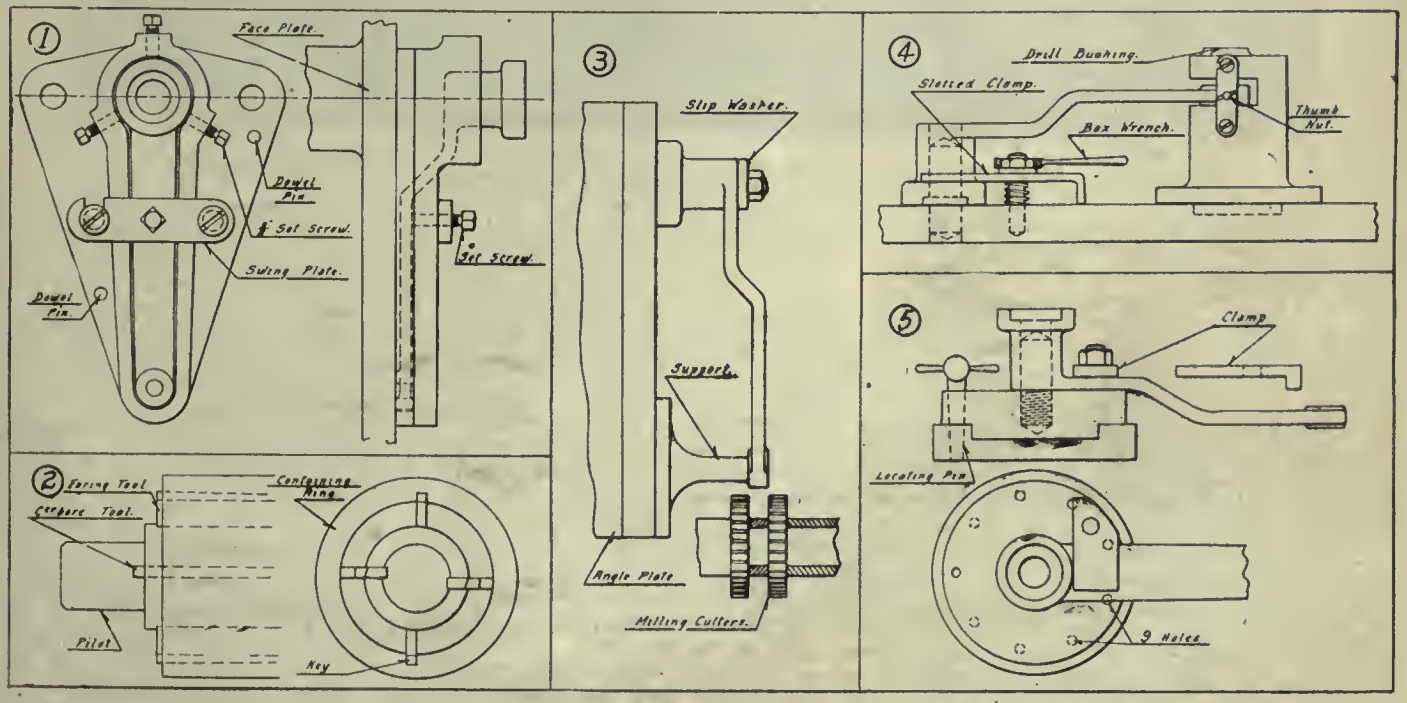
1.—Lathe operation on the large end drill, ream, counterbore, turn outside and face. 2.—Face both sides of the boss on the small end with a pair of milling cutters. 3.—Face the back of the large end on the drill. 4.—Drill the half-inch hole in the small end. 5.—Mill the teeth.

The first operation would require, first, a small fixture to bolt on the faceplate of the lathe for quick setting up. Fig. 1 shows this fixture. It is bolted to the faceplate by two ⅝ bolts, and prevented from sliding by two dowel pins. The piece is placed in the casting as shown.

The casting is made to form, and bored out in position a little larger than the boss, enough to give a working clearance, and held in position by three set screws and a plate. To remove the piece, the top set screw only is loosened, and the plate is allowed to drop down. The outside turning is completed while the drill is being fed through. After drilling and reaming, the counterboring and facing is accomplished with a tool which has a pilot to fit the hole.

Fig. 2 shows construction of this tool. It is a piece of tool steel turned the required shape with a one-inch pilot on the end. Four slots are milled longitudinally to take four pieces of high speed tool steel, and on the outside a containing ring is turned to fit. These tools can be adjusted and are held in position by keys. This tool has the great advantage that in case of breakage it can be pushed further out until the high speed steel is practically worn away. This is the major operation and would occupy about ten minutes.

For the second operation we will take an angle plate and screw into it a one-inch hardened steel pin, threaded at the end for a ⅝ nut. This nut is to be made so that the casting will pass over it without having to remove the nut. A slotted washer is inserted between the



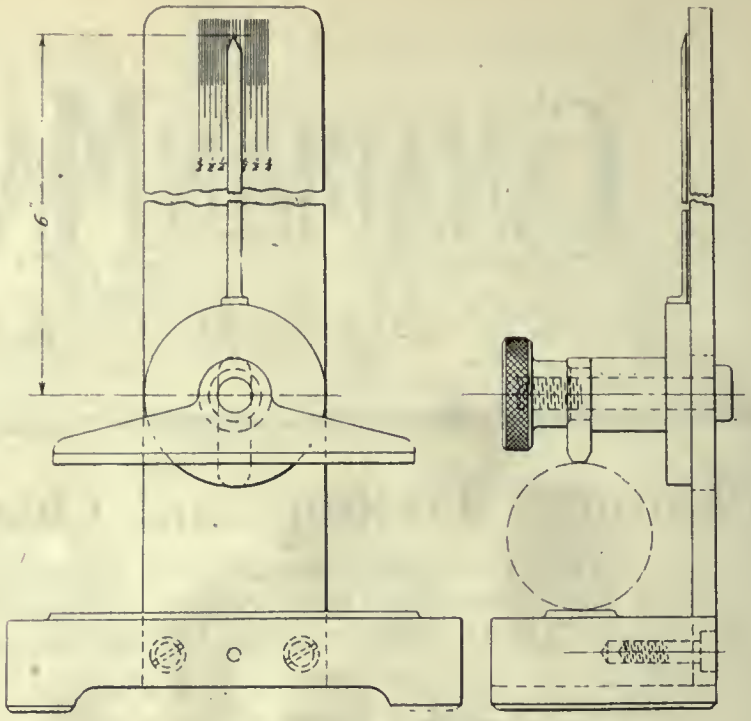
FIGS. 1 TO 5—ILLUSTRATING HOW THE AUTHOR WOULD COMPLETE THE LEVER.

nut and the casting to enable us to tighten up the work.

Some sort of support will have to be provided for the small end to bear on, and the direction of rotation of the milling cutter arranged to thrust the work downward. The angle plate must be bolted to the milling table, so that the distance between the faces after the first piece is completed will come automatically correct. The time for this should be about two minutes.

The third operation, namely, facing the boss, and the fourth operation, drilling the half-inch hole, could be done on the same jig. If a round 12-inch blank flange could be picked up somewhere it would serve to build this jig upon. If not, a casting would have to be made. Drill and tap the base for 1-inch cast steel pin. Make the pin about one and a half inches long. This would leave room for the pilot on the facing tool. Swing the small end on to a boss or raised piece, the right height, and up against a stop, when the piece would then come directly under a hardened drill bushing properly located. It could be held in place by some locking lever device such as at Fig. 4. Time for the two operations, three minutes.

The final operation is milling the nine teeth. The very fact that there is an odd number of teeth allows us to run right across the face with the milling cutter and cut the side of one tooth and the opposite side of the other, and takes nine cuts. If we have any horizontal indexing attachment, the problem resolves itself into one of quick and accurate setting up. If there is no suitable fixture belonging to the milling machine, then a simple holding and spacing jig could easily be made by taking two plates. Make one rotate round the other, hold the work on locating pins and drill nine holes in for spacing. See Fig. 5. Time, about six minutes. Total time, approximately twenty minutes.

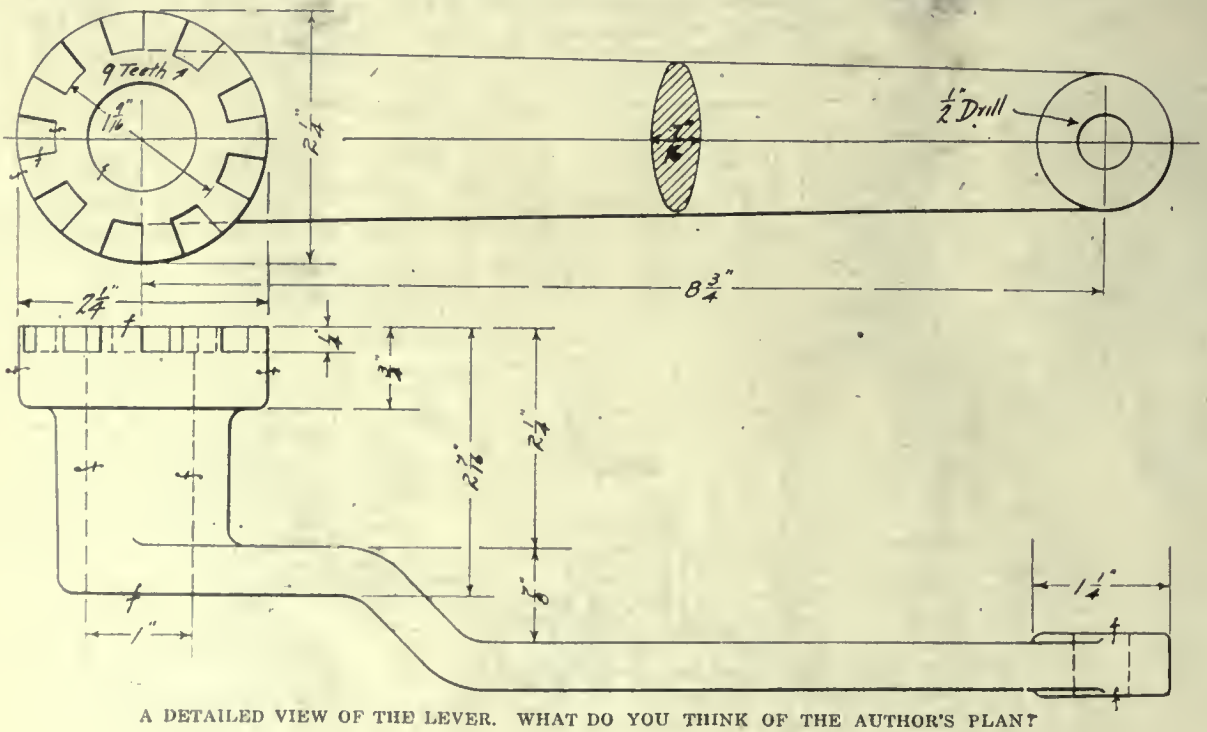


TAPER MEASURING DEVICE.

TAPER MEASURING DEVICE

By John Homewood

The occasion often arises when it is desired to know how much taper there is on a certain piece of work. Very frequently this is required when a piece is wanted for replacement. Many methods for ascertaining this taper are laborious and subject to mistakes in calculations. The sketch herewith illustrates a simple bench gauge that should be a valuable asset to any shop using tapers. The details of construction, and its action, are self evident, and need little explanation. The upright that extends from the rear of the base carries the adjustable swivel bar and the indicating finger, that shows at a glance the amount of taper that is on the work. The working faces of the gauge are hardened and ground and pointer should be set to zero by means of a cylindrical standard.



A DETAILED VIEW OF THE LEVER. WHAT DO YOU THINK OF THE AUTHOR'S PLAN?

Practical Pointers on Rolling Mill Operation

English and American Methods of Rolling—Getting Large Output in Rolling Thin Plates—How to Avoid Waste—Universal and Plain Mills—How to Obtain the Best Results

By W. S. STANDIFORD

AMONG the vast diversity of metal products turned out by the various rolling mills, the rolling of ship plates, automobile sheets and strip steel occupies a front rank position. In view of the above, readers will undoubtedly be interested in reading about roll designs, difficulties encountered in rolling, and other factors entering in the production of the above metal sections.

The term "sheets" is generally applied to flat pieces of metal such as iron, steel or the non-ferrous varieties which are less than one-fourth of an inch thick. From one-fourth inch and upwards, the metal is called "plates," tin plates being an exception to this, the term being applied to very thin sheets of iron and steel which are coated with tin, or a mixture of lead and tin. Plates are rolled in various lengths, their dimensions being limited to the railroad transportation facilities, such as the sizes of cars. There are two styles of plates sold on the market, viz.: "Sheared" and universal plates. Sheared plates are wide ones as rolled in the mill, they being cut to certain sizes in widths as desired by the consumer. In all plate mills there is more or less waste of metal due to the plates having imperfect edges. The economical working of any plate mill depends largely upon the percentage of the metal which has to be sheared from it to remove the imperfect edges.

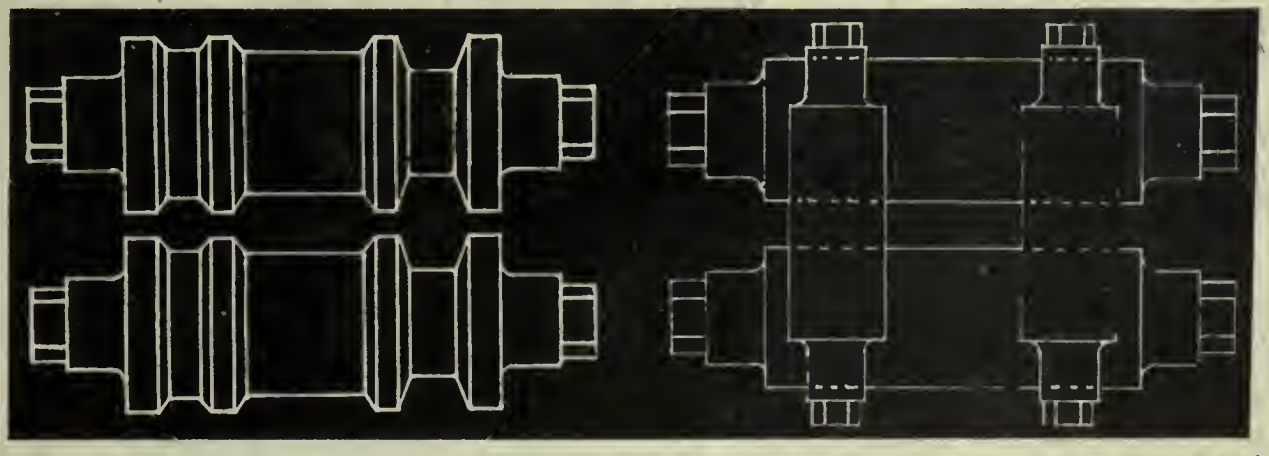


FIG. 1—LEFT HAND VIEW. A TWO-HIGH SET OF BLOOMING MILL ROLLS.
FIG. 2—RIGHT HAND VIEW. ILLUSTRATING HOW THE ROLLS ARE PLACED IN A UNIVERSAL MILL.

Avoiding Shear

To avoid having to shear any metal whatever from the sides of long and narrow plates, they are most generally rolled in a "universal" mill. Plates as high as one hundred feet long by six feet wide, and one-half an inch thick down to one foot wide, and one-fourth an inch thick, are produced in this way. The waste of plates rolled on a universal mill will average about 15 per cent. less than those rolled on the average plate mill. The length and thickness of plates which a mill can turn out is independent of the dimensions of the rolls, but the width is determined by the length of their barrels. Thus a 150-inch mill means that the mill will roll a plate 150 inches wide. Plates can be rolled from ingots or slabs, both giving very good results in the finished product. They can be rolled in either two high, or three high mills, the English using the two-high system. In most cases, it is the usual English practice to have a separate set of roughing rolls connected up by means of boxes and spindles to the finishing ones, the rolls being driven by a reversing engine. The reversing engine is not an economical piece of machinery to run, but it seems to be well liked and largely used by English plate mill manufacturers.

The New Plan

The English plate manufacturers formerly used to roll the hot ingots directly into plates without their being reheated, but of late years they have adopted the plan of rolling the large ingots into slabs of four inches or more in thickness, then cutting the slabs while hot into the desired lengths and stored away until required. When needed, they are put into a heating furnace to raise their temperature for the final rolling. More fuel is consumed by the latter method; but, on the other hand, fewer defective plates are made, and taken in general, there is much less strain on the machinery than is the case when the ingot is rolled in one heat, which is the case with the American system of plate-making. These advantages are generally considered by English manufacturers to be more than an offset for the extra amount of coal consumed.

On an English plate mill, the same crew does the roughing and finishing. The crew works the cut slab until the roughing rolls reduce it to a suitable thickness; it then is transferred to the finishing rolls. Two crews cannot be used on this style of mill for the reason that the jerking and uneven action of the roughing rolls interferes with the smoothness of the surface finish of the plates and also with the uniformity of gauge thickness, the plates being rendered with great variations in thickness, hence the advisability of doing the roughing by itself. In the English system the rolls are worked dry, no water being used upon them. This necessitates turning the rolls slightly concave in the middle in order to allow for expansion as the metal expands in the middle more than it does upon the ends of the rolls. When a mill of this type is first started up on a Monday morning, it is customary to roll narrow plates at first so as to get the rolls gradually heated and expanded to a level surface. The general practice in America is to finish sheared plates from ingots or slabs—without re-heating them—on one stand of rolls, the three-high system being used and running water being employed to cool them and prevent overheating and undue expansion.

It may be thought that the use of running water on the plates would cool them very quickly and interfere with their reduction in thickness. The water does not cool these plates as much as might be reasonably expected, because the heat of the plate suffices to maintain the water in a spheroidal state, thus pre-

venting any close contact between the two.

Water Has Beneficial Effect

Water on iron and steel plates during rolling has a beneficial effect, as it loosens and causes the scale (which contains impurities) to break away from the metal. Iron plates while being rolled contain more scale than the steel ones. This is due to the fact that iron is more impure and porous than steel and it contains lots of cinder and slag, which are worked out by the action of the rolls. Scale on plate, whether of iron or steel, when being rolled, is a nuisance, especially near the finishing stage, because if it is not swept or blown off by compressed air it will invariably mark the finished product. This is due to the fact that the pieces of scale laying on top of the plate will be rolled sufficiently into the surface as to make a slight depression on it. When a set of rolls are used for both roughing and finishing purposes, the wear on the same is greater than is the case where a separate set of rolls are used for roughing down the ingot, as the drafts used are far heavier in the roughing down process. The result of this is that the rolls have to be dressed at more frequent intervals when they are used for both roughing and finishing.

Rolls in Tandem

The American system of using running water to cool plate rolls obviates the necessity of turning them with a concave surface as is used in the English system. When thin plates are to be rolled, the largest output is secured by using a separate stand of finishing rolls, and placing the roughing set in tandem. In this case each set is driven by its own engine, or an electric motor as the case may be in that particular mill. All sets are also in line with each other and connected by tables. By this method, the finishing rolls can be run at as high a speed as is practicable; which not only gives a better surface to the thin plates, but allows a greater output to be secured. The work of the roughing rolls can be so distributed as to synchronize with the time cycles of the roughing and finishing mills. One of the most well liked and generally used types of plate mills is the "Lauth" mill. This is a three-high mill with one stand of rolls. A unique feature of this mill is the manner in which the middle roll is used to support the top and bottom rolls when they are in action. The top and bottom rolls of the mill are 34 inches in diameter and are both of driven variety, while the middle one, which is 24 inches in diameter, runs loose and revolves by friction with the plates being rolled. It is raised or lowered by a hydraulic cylinder to enable the plate to enter the rolls between the middle and top, and the middle and bottom rolls. As the middle roll is ten inches smaller in diameter than the top and bottom ones, it is pressed against the surface of the top roll when the hot steel is being rolled, the thickness of metal in the top roll preventing the middle one from boiling.

Another important point is due to the fact that as the middle roll is smaller in diameter, it has a sharper periphery or contact of surface than both the top and bottom rolls, the result being that the middle one bites deeper into the metal being rolled, thus it has a more rapid reducing action than the larger diameter roll whose periphery is flatter and does not elongate the metal to the extent of the smaller one. In practice, the Lauth mill has been found to be very efficient and it gives good results, being used extensively. This type of mill is made to use cast steel slabs, which are tapered slightly so as to permit of their removal from the ingot mold in which they are cast. As there is no means of edging the slab, the top roll not lifting sufficiently for the purpose, it would naturally roll out a plate that would be wider at one end than at the other, did not the roller take advantage of this fact, that in rolling metal the piece rolled is extended in length, but not appreciably in width.

VALUABLE ADVICE

The author of this article is a practical rolling mill man himself, and knows whereof he speaks. His information is brief and to the point. An article of this nature is well worth filing away for future reference, as it contains many valuable pointers in rolling mill operation. This is only the first part of the article. It will be concluded in our Jan. 6th issue.—Editor.

Bringing Slab to Width

One way to bring the slab to an even width would be to insert it between the rolls, having its long side parallel with their axes. But the main drawback to the method exists in the fact that the slab is too narrow and not wide enough to allow of its being carried sideways on the ordinary roller tables that are supplied with mills of this kind. As it is absolutely necessary, in order to prevent a waste of metal in the finished sheets, that the slab should have an even width at the start of rolling, it is inserted diagonally in the rolls with one corner facing upwards. This reduces it to a diamond shape, it is then turned over by the manipulator and entered on the opposite diagonal corner, with the result that the second reduction has again squared the slab, the process spreading it in both directions. If necessary, this operation is repeated several times by the roller. It all depends upon the amount of carbon that the steel contains, thus affecting the drafts. A slab rolled by this method has a uniform width. The rolling is now resumed in the ordinary manner until the plate has been reduced to the desired gauge. We now come to the design most generally used, namely, the two-high set of blooming mill rolls to reduce ingots for making into slabs and billets. These are illustrated in Fig. 1.

This set of rolls is shown in sketch as having one extra wide slabbing pass in the centre, and two different sizes of billet grooves. As a matter of fact, five or more passes could be cut into the rolls, depending upon the size of the billets desired and also the width of slabs produced. It will be noticed in the sketch that the corners at bottoms of passes are left sharp. This was done in making the sketch to save as much work as possible, the idea being to show the appearance of this type of rolls only. In actual practice, the roll turner always puts rounded fillets at the corners of passes in this style of rolls. This is done so that the corners on the ingot will be worked as much as possible and have a fibrous nature.

Should Be Turned Over Frequently

Rolls of this design are used all over the States and Canada, also in other countries. They are used for reducing the large ingots, the latter being worked in the slabbing pass as they come from the furnace. The ingot is turned over on its side, each one alternately rolled until, if billets are desired, the metal is sufficiently reduced in area to allow it to enter one of the billet passes. It soon gets reduced to a long rectangular shape in these grooves. In order to have the edges of the finished material as free from cracks as possible, it should be worked as rapidly as can be done while it is at a high heat and be frequently turned over so as to facilitate the metal getting into a fibrous condition, which is the object desired by all iron and steel manufacturers.

The slabbing pass in these blooming rolls are put in level by the roll turner, which is the case in rolls used in some mills. In other cases, however, the pass is a convex one; the highest part being in the middle. This design makes an excellent working pass, which does not strain the machinery as much as does a groove having a straight bottom. As the ingots in all blooming mills are turned over at a right angle to the previous position which they occupied, in order that all of their four sides should be thoroughly compressed, the two concave sides of the ingot when being rolled at a right angle to the axes of the rolls, straighten up when their top and bottom are being compressed in the roll pass.

If the ingot is being reduced in a slabbing pass, the metal, owing to the heavy drafts used by the roller, bulges

out at the joints of the rolls. When the bulged or uneven side is turned over and faces the top and bottom roll slabbing pass, it lies over at an angle out of a perpendicular line to the roll axes and not at a right angle on the feed rollers. Should the draft be reasonably heavy, the ingot is apt to turn over in the groove altogether while being reduced. The result is that the ingot is mashed out over the collars of the roll pass next to the one in which the rolling is done, and if the engine is very powerful the roll is either broken or badly bent so that it cannot be used again. On the other hand, if the ingot has its concave sides resting upon the feed rollers, the position of the ingot will be at an exact right angle to the roll axes and also feed rollers, the ingot resting on its corners only, its centres not touching the feed rollers at all.

Gives Fine Results

The advantage of this is that the concave surface of the metal allows the ingot to be easily gripped and quickly dragged into the pass, the merits of curved passes for this class of rolls being of the utmost importance as regards the rapid reduction of steel and it gives fine results under actual working conditions in every class of mill using this style of roughing grooves.

Slabbing and plate mill rolls depend mostly for their drafts on the amount of up and down play which their housings and mechanism permit, it being in the roller's power to use either light or heavy drafts as is considered necessary. It is the usual practice to reduce the steel quickly as possible while rolling. Many rollers in their eagerness to get their day's work done as soon as possible abuse the rolls and machinery by reducing the metal at the utmost possible limit of drafts, which rolls and machinery will stand, thus throwing a continual strain upon the apparatus. The danger of ruining rolls by twisting necks off of wobblers as well as damaging the housings and engines is one that a roller will take risks upon when he is at work, as it seems to be a peculiarity of human nature for men to be careless with other persons' property. By watching the workings of the rolls from a position where the roller cannot see him, a works manager can easily find out for himself if his roller is handling his machinery roughly. When extra heavy drafts are being taken, a heavy cloud of black dust will arise from the rolls while they are in action. This is an infallible test, the black dust coming from the pass surface which is being ground off by the hot ingot metal, which has reached its utmost limit of resistance. The machinery will also be heard to vibrate heavily and make more than the usual amount of noise when extra heavy drafts are being used.

A Waste of Money

Rolls roughly handled require an extra amount of metal taken off by the roll turner when dressing, in order to bring the passes into shape again. Thus there is another waste of money which is totally unnecessary. In working of blooming mill rolls, it is much better to operate them at their maximum safe rate of reduction, which they will stand. A steady, even pace, with no interruptions caused by breakdowns, is much better than a spasmodic effort being made to break tonnage records with its evils of straining the machinery, that sooner or later causes a shut-down ahead of its time for repairs. Excessive reductions also produce slabs that are thicker in their centres than at their edges. To give an idea of the amount of wear that a set of normally used blooming rolls undergoes while they are rolling all kinds of ingots comprising both soft and hard steels, the following measurements were taken from a set of worn rolls that were sent to the roll lathe to be dressed. These rolls contained four billet and one slabbing pass; the sides of the billet grooves being worn out 3-16 of an inch wider than a templet which is used by the roll turned to keep them the same width. It will be observed in the sketch of blooming mill rolls that the grooves have tapering sides. There is a two-fold object in putting them in with tapering collars, namely that by having grooves with slanting sides, the hot metal touches a bottom point of the groove before it grips the wider part at top, the result being that there is no shearing of metal from ingot at the top part, which would be the case if the groove sides were straight, the sheared metal from ingot coming off in the form of narrow splinters.

Sides Parallel With Roll Axes

Should they be put in the rolls straight—that is, having their sides parallel with the roll axes, and they wore out 3-16 inch at their sides, it would be impossible to make them fit templets no matter how much metal was taken off of the rolls in turning. To make these worn roll grooves again fit their templets, it was necessary for the writer to take 11-16 inch from the collars or tops of the rolls. A corresponding amount was removed from their bottoms so as to keep the depths the same. In regard to the total amount of time consumed in doing this work on both rolls, it required 4½ days, the tool used having a width of 3½ inches.

The roll lathe was driven by a 15 h.p. direct current electric motor, the latter having more power than was really necessary. The writer while doing the turning desired to know the exact amount of power that was needed, and had the chief electrician discover the amount necessary to operate the lathe on both roughing and finishing cuts. With the above width of tool, it took 7 h.p. to sustain a steady roughing cut and 3¼ h.p. for the finishing one. Each roll was 26 inches in diameter and weighed over 8,000 lbs.

A type of mill also much used in this country is called the "universal" mill. It is adopted extensively for plate-making and jobbing work. This mill consists of a pair of ordinary plain cylindrical rolls mounted in the usual way, and at the back of these a shorter pair of similar rolls, which are mounted with their axes in a vertical position; so that they will compress the edges of the bar at the same time that the horizontal rolls compress it on its flat sides. This arrangement obviates the necessity of the ingots having to be turned over on their sides so as to work the edges that face the joints between the collars of rolls, which is the case with slabbing rolls.

The vertical rolls are, as a general rule, made smaller in diameter than the horizontal ones, and they are driven from their upper ends by means of mitre-wheel gearing which operate other bevel gears keyed onto a shaft crossing the top of the housings. On the end of the shaft is a spur wheel working into the upper pinion in the pinion housings, or with a spur wheel keyed to it. Originally, the vertical rolls were driven from their bottom ends, but scale from the steel being rolled kept falling into the gearing and caused the teeth to wear out rapidly so that they are now driven from their top ends. Fig. 2 illustrates how the rolls are placed in a "universal" mill, no gearing being shown in the sketch.

Width or Thickness

It will be seen from this combination of four rolls that any width and thickness of flat plates within the compass of the mill can be produced with equal facility. Universal mills generally make plates up to 6½ feet wide. Of course, there can be wider plates made by this method of rolling if the rolls are made sufficiently wide and thick in proportion to the work that they have to do. Plates made on such mills usually have their edges straightened by pressing them while hot on the floor between two bars, which are squeezed against the plates laterally. If the piece of metal rolled in a universal mill is not entered by the roller perfectly square, or if it bears much harder on one vertical roll than on the other—it will be curved in a horizontal direction; and the same thing will occur if the plate is unevenly heated; the hotter side elongating more than the colder one, and once it is bent it is not an easy matter to straighten it. The effects of uneven heating in the working of the steel in the rolls, shows in the finished product, it being of vastly greater importance that the material shall be uniformly heated, even if it does take more pounds of fuel to do it. Unevenly heated and crooked plates not only give trouble in turning them over and handling them on the castors, but their

thickness varies in different parts, which is due to the many hot and cold spots on the plate. When the outside of a plate is cold and its interior hot, this condition causes the rolls to spring and the housings to stretch appreciably when rolls reach the cold spot. It will readily be seen from the foregoing that it is a very difficult matter in the case of long plates to keep the gauge thickness uniform, so that if one end of a long plate is much colder than the other, it will be found to be thicker than the other.

When very thin plates are rolled this is a constant source of trouble, for in the manufacture of thin plates and long narrow strips, they cool so rapidly that their last ends are always colder and thicker than the first. In the universal mill the speed of the surface of the vertical rolls located at the back of the housings must be greater than that of the horizontal ones through which the bar is passed, the amount depending upon the extent of the draft which the roller uses at each pass. Any deficiency of the surface speed of the vertical rolls will prevent them from passing the metal contained in the bar as fast as they received it from the horizontal ones, and it would—if thin—accumulate in a mass of crumpled and bent steel between the rolls and be spoiled.

To avoid this, the vertical rolls should always be run somewhat faster than is required theoretically, which is a matter depending upon the skill and judgment of the roller if good results are to be obtained. As it is impossible at times to guard against a workman using too much draft at a pass, its speed must in practice be very much in excess of the correct amount. On the other hand, if the speed is too great this involves much slipping of the edges of the bar against the surfaces of the vertical rolls, which rapidly wears them out and absorbs much power uselessly, causing a considerable "backlash" which is very destructive to the gearing.

Avoid Backlash

Backlash on rolls takes the form of a succession of slips and jerks. Even if the surface speed of the two sets of rolls is correctly proportioned when they are new, the relation between their diameters is soon destroyed as they are turned down too correct for wear; as vertical rolls do not wear evenly with the horizontal ones.

It is the usual practice in most mills using steam power to operate their rolls to drive the horizontal ones by a reversing engine, while the vertical rolls are driven by a second separate set, but of less power. Taken all in all, the universal mill is not an easy one to work, much skill being needed on the part of the roll adjuster to keep the same working smoothly. Constant vigilance must be exercised on his part as the bearings and roll surfaces keep wearing and need looking after. The advent of the automobile has created a demand for sheets of the highest grade and quality, a demand which is exceedingly costly and difficult on the manufacturer's part to meet, as in the rolling of these sheets there are always some that contain slight imperfections such as surface blemishes, buckles, roll marks, furnace scale, pitting caused by the rolls wearing down near the end of the chill depth, and also dirt dropping on the metal from the point of the workman's tongs, which are allowed to rest upon the floor while metal is getting heated.

Sheets having slight imperfections are termed "seconds," and in order to make any money at all on this class of sheets the manufacturer generally insists that the automobile plant absorb a small proportion of these seconds, a price reduction being made on defective ones. Automobile sheets are mainly divided into three classifications. Number one is called body stock. The second is termed splash-guard, hood, door, apron and flat fender stock. The third, crown fender, radiator casing and cowl stock. There are further subdivisions of these classifications that consist in the steel analysis and also the hardness of temper which is imparted to the sheets by cold rolling. The bars from which automobile sheets are rolled are treated differently from those used to make ordinary ones, such bars being pickled in acid so as to remove scale and other dirt. There are also many other operations gone through, such as repeated picklings and annealings that the ordinary brands of sheets used for other purposes do not undergo.

Each mill that manufactures sheets for the automotive industry has its own method of getting results, but they all resolve themselves into rolling and producing the highest grades of sheets that are possible. Cold rolling figures largely in the obtaining of a high finish on sheets, but it also has the drawback of hardening the steel to such an extent between successive rollings, which are necessary to reduce the metal to the desired gauge, that frequent annealings between each rolling are required, otherwise the metal would become very brittle and crack.

Even the softest quality of steel is hardened or stiffened by means of hammering, drawing, or cold-rolling. Cold rolling increases the elastic limit and ultimate strength but also decreases the ductility. Body steel is divided into the following varieties or classifications: bright finish, and velvet or dull finish. These are again divided into standard stamping or drawing metal, deep drawing metal, and extra deep drawing quality. The bright finish is a glossy shining surface and it is intended for japanning or enameling. The velvet surface sheets have a grain that is more or less open, which is intended to hold the paint, these sheets being made for hand coating. The painting operations are priming, rough stuffing and an air-drying enamel that needs no baking. Such sheets are admirably suitable for work of that character. The deep drawing quality is also used for parts that have shallow depth. Back and side panels usually are made from this quality of steel. The extra deep drawing quality of metal is produced for very difficult drawing operations such as seat backs, wheel housing, and other parts. The seconds from this class of sheets can be used by glazing over the imperfections with putty. Door, apron, splash-guard and fender-stock are made from a grade of sheets that need to have a very high finish as it has to be enamelled or japanned.

This grade of sheets has a closer grained surface than the body stock, but it will not stand much bending and it should be used for work that has no very sharp angles and that is comparatively flat. Deep drawing and extra deep drawing steel ought to be ordered for work requiring deep bending. After sheets for automobile bodies have been rolled they are next run through a series of small rollers to straighten them. This process removes any small buckles or strains that were caused by uneven annealing or other causes.

Making Sheets Straight

This method of straightening does not leave them absolutely flat. To make them level it is necessary to stretch them in a hydraulic operated device called a "stretcher leveler," which makes them absolutely straight and flat. It is not necessary to use stretcher-levelled sheets if they are to be drawn through dies, as the drawing operation will usually absorb any small buckle in the metal, providing the sheet is not badly or deeply buckled. As the sheets made for automobile manufacturers are liable to rust while they are in a warehouse, they should be oiled and crated ready for shipment.

Most automobile sheets are made in Nos. 19, 20, 21 and 22 United States standard gauge, and should be ordered in that gauge and not in thousandths of an inch. The writer believes that the time is coming when some of the alloyed steels such as vanadium, chromium, etc., will be made into sheets for motor cars as it certainly would have great advantages in regard to lightness and strength. If the new stainless and rustproof steel could be used in sheet form for automobiles it would give good satisfaction, as once the enamel peels off of the ordinary sheets used in our autos it doesn't take long for rust to form on the metal's surface, the result being that when a car has to be re-enamelled it takes a lot of work to make a smooth job on the rust spots. Using rustproof sheets would save a lot of time and money in this respect.

To Be Continued

Increasing Production With Pneumatic Tools

The Selection, Operation, Maintenance, and Repair of Pneumatic Tools Are Important Points. Different Methods of Driving Rivets, Method of Starting Hammer, Etc., Etc.

THE need of accelerated production in the shipbuilding and engineering industries has resulted in a greatly increased use of the portable pneumatic tool (which has now been developed to a very high degree of efficiency). Pneumatic tools with their percussive action are peculiarly adapted for riveting, chipping, caulking, etc., and are extensively used in shipyards, on bridge and constructional work, while in foundries and steel works their value for fettling castings and removing seams from billets is fully recognized.

The selection, operation, maintenance and repair of pneumatic tools are subjects which demand careful consideration. The hammer selected should be powerful and rapid in action and should operate with a minimum of vibration. The design should be well balanced and the form of the tools such that they are convenient to hold and guide without undue fatigue. The driving of rivets with a pneumatic hammer is a strenuous job and calls for a man of strength and stamina seasoned by experience.

The riveting hammer may weigh anything from 16 to 25 pounds and will strike from 600 to 1,000 blows per minute. The length of stroke varies for different hammers between the extremes of 5 and 9 inches. For general purposes, however, it may be assumed that a hammer of 6 inch stroke will answer most needs in a satisfactory manner. Vibration is unavoidable in a pneumatic hammer, but in modern designs this trouble has been reduced to a minimum. Excessive vibration greatly increases the difficulty of holding and guiding the tool, and, of course, occasions the operator undue fatigue.

There are two methods of driving rivets at present in use on shipwork, first, the "two man hand gang" method, and, secondly, the one man "pneumatic machine" method. Driving rivets by hand requires natural aptitude, training, and experience with the result that, generally speaking, the hand gang riveter is probably more adept than the machine riveter and this is undoubtedly the reason why hand riveting has in the past been considered superior to machine work.

One authority has said, "Give a good machine riveter who understands his business a good pneumatic hammer, proper air pressure, well heated rivets, and he will do more work than the hand gang, with the results equally good."

In the actual driving of rivets the results depend largely upon the skill of the man operating the tool. Given average endurance, however, almost any man of reasonable intelligence can quickly learn to perform the operation with success. The points to be observed in riveting, if good tight joints are required, are as follows:

The holes must be practically in line. The plates must be well bolted together. The rivet heads must be well up against the plates. The rivet must be hot enough to expand and fill the hole for its entire length when driven. The holding up device must keep the rivet firmly in position. The riveting hammer must have sufficient power and speed to form the rivet before it becomes too cold to fill the hole.

A rivet which is loose in its hole may be caulked up to pass test, but will not carry its estimated proportion of the load under stress, and a large percentage of such rivets will lower the efficiency of a joint to the danger point.

POINTS TO REMEMBER

Pneumatic tools with their percussive action are adapted for riveting, chipping, caulking, etc. They are used in shipyards, bridge and construction work, while in foundries and steel works they can fettle castings, and remove seams and defects from billets.

Be careful in selecting the tool to get one suited for your work. After you get it, take care of it. A tool cannot do good work if it is not cared for properly. The most trifling faults are liable to throw pneumatic tools into disorder, causing them to stick and kick.

When rivets fit easily in the holes, and the latter are clean cut and sound on the head side, excellent work may be performed by the use of a simple pneumatic "holding-on" machine. In repair work, especially where old rivets have been cut away, these conditions do not hold good, and it will be found that the holes are ragged on the head sides, preventing the rivets from being pushed home.

In these circumstances recourse may be made to one of the hammer or jam holding-on machines in which the thrust cylinder is combined with a hammer which may be operated to drive up the rivet and then shut off without interfering with the thrust. In button head riveting, the head assists the operator to hold the hammer in place, but when flush riveting is required, such as is used on the outside of a ship, the hammer must be guided and controlled without this assistance.

The appliances known as shell rigs are frequently resorted to in these circumstances for supporting the hammer when on the outer shell of a vessel. In driving button headed or cone headed rivets, the machine should be sufficiently powerful to form perfect heads without rocking to work down the edges. The hammer should be started off lightly until the rivet has settled somewhat into the hole to prevent bending to one side.

The following are actual times taken to drive button headed rivets with an AW No. 6 riveting hammer: ¾ inch diameter rivets, 3 to 4 seconds; 1 inch diameter rivets, 5 to 6 seconds; 1¼ inches diameter rivets, 12 to 14 seconds; 1⅜ inches diameter rivets, 17 to 20 seconds.

The necessary equipment for driving flush rivets includes a pneumatic chipping hammer and several chisels for cutting away the surplus material. The difficulty of driving flush rivets, is the necessity of getting the rivet's head to a point in order that the surplus metal may be chipped off while it is still hot and soft. The operation is complicated by the difficulty of holding and guiding a flat set on a flat surface.

The duty of the holder is to ensure that the rivets are placed in the holes hot and that the heads are well up to the work conditions, which are essential if good tight work is to be done. For general use with air hammers the "pneumatic holder up" is coming into increasing favor. The construction of these tools is very simple. A solid piston of about 3½ inch diameter works in a shoot cylinder, and is operated by compressed air at the same pressure as that used for the riveters. One end of the piston carries a snap or die adapted to fit the head of the rivet, while the other end of the machine is extended by screwing on suitable lengths of tubing to reach some solid backing. Upon opening the valve, the piston moves outwards and the rivet is firmly pressed into position.

As previously remarked, there are other forms of pneumatic holders in which percussive action is available in addition to thrust, which are of value where the holes are tight or the plate surface unlevel.

The maintenance of pneumatic tools is an important subject which is not always given the care and attention it deserves. The pneumatic tool store should be equipped with a plentiful supply of spare parts and such accessories and conveniences as experience has shown to be necessary, while repair men should be competent to remedy all minor

defects with a minimum of delay. Only a small percentage of repair men ever learn exactly why or how pneumatic tools operate, but they can all learn to keep them in their original condition as delivered from the factory.

Even this is not such a simple matter as it would appear, but it may be accomplished with a little care and observation. The most trifling faults are liable to throw pneumatic tools into disorder and cause them to stick and kick or start badly. As bad tools invariably lead to bad work, it is important to impress upon workmen the necessity of at once returning defective hammers to the stores. When a hammer kicks and sticks or is otherwise out of order, a riveter may frequently put up with it rather than risk the delay involved in journeying to the store for another tool, and as a result work is done which later may have to be caulked or cut away.

When machines are returned for cleaning and adjustment, the repairer should carefully examine surfaces which fit together to form air-tight joints, remove any burrs with a fine flat file, take away sharp corners, and slightly countersink pin holes. He should try, on a heavy block of wood arranged for this purpose, one of the hammers which is known to be in first-class working condition. With the working characteristics of this machine as a standard, he will readily learn how fast a machine should run, how much vibration is to be expected under normal conditions, and how rapidly the steel should cut into the wooden block when the machine is developing its full power.

With these standards in mind the repairer can test doubtful machines and judge by comparison whether they are right or wrong. A good repairer will become so familiar with the machines under his care that he will be able not only to state positively if they are in good or indifferent order but to readily diagnose faults. When a machine has plenty of power, but is slow, kicks, or refuses to start promptly, it will be generally found that the piston or the valve is not working freely. When in good order the piston should slide the entire length of the cylinder when tilted by reason of its own weight. If it fails to do this an examination will usually reveal high places on the pistons which are fouling the cylinder walls. These should be carefully reduced by rubbing with fine emery cloth. Rough spots on the cylinder walls should also be looked for and treated in a similar manner.

The valve should be carefully examined for burrs or high places which would prevent it from shutting closely on its seating and it should be noted that it is sliding freely through the whole length of its travel. A badly seated valve permits an escape of air which, although apparently insignificant, will be sufficient to cause a hammer perfect in all other respects to work badly. If the valve is working too easily it will open and close the ports and so reserve the flow of air before the piston has had time to follow its action, and care should therefore be exercised in easing a tight valve to ensure that the operation is not carried too far.

It is assumed that the repairer will clean out all drilled parts and pin holes, being careful not to overlook the smaller ones. It frequently happens that a mysterious loss of power may be traced to a leakage occurring between faces which should form airtight joints, this being owing to the edges becoming burred by careless handling. Such burrs should be removed by means of a smooth file and the faces tested for inequalities by the use of a little blacking. Occasionally the failure of a hammer to start promptly may be traced to leakage at the throttle valve situated in the handle.

Such a leak, by filling the ports and passages of the hammer with live air, forces the piston to take up a position in the middle of the cylinder covering the exhaust ports, with the result that when full air pressure is applied the piston remains stationary in this position. Usually a tilting of the hammer combined with a slight tap is sufficient to overcome the equilibrium of the piston and start the hammer, but a machine which persistently exhibits this fault should be fitted with a new throttle valve without delay.

It may be taken as granted that the only way to ensure that pneumatic tools are properly cared for and maintained in good order is to insist upon their return to the stores at the end of each day's work. The repairer will then run each machine for a few moments and lay aside for further investigation any which in his opinion exhibit signs of disorder.

Those passed as satisfactory should be arranged on racks and lowered bodily into a tank of mineralized oil for the night, thus ensuring that no internal corrosion can take place as a result of the condensation of moisture from the air supply. It will often be found that a simple soaking in a tank of mineralized oil for a period of fifteen minutes will remedy a defect and obviate the necessity of dismantling a tool for repair.

Many of the foregoing remarks apply with equal force to other types of pneumatic tools as well as to riveting and chipping hammers, and the question of maintenance and repair should receive the most careful attention if good work and high efficiency is to be obtained from an installation.

LARGE STEEL PLANT

A huge electrically driven steel plant called the Winshu works, situated at Yawata, Japan, have had their equipment sent from the United States, the estimated cost being $3,700,000. The initial plant will include three 50-ton basic open-hearth furnaces, a 20-unit producer plant, an 84 in. plate mill, and a 24 in. structural mill. A motor-driven 35 in. blooming mill is to be installed later. The three basic open-hearth furnaces will be served by twelve Smythe gas producers. The 84 in. three-high plate mill, which is nearing completion, is of the Lauth type, and will be driven by a 2000 horsepower motor through herringbone reducing gears and pinions; the motor running at 420 revolutions per minute makes the mill speed 56 revolutions per minute. This company has its own blast furnaces, coal and iron ore mines, and firebrick plant in China, so that it will be the most completely self-contained organization in the Far East.

USEFUL INFORMATION

Where should I use Babbit, and when should I use bronze? If you have ever asked yourself that question, read what Brass World has to say on the subject. Babbitts as a class show high plasticity combined with low Brinnell hardness and compression strength, and these properties limit their application. Bronzes are therefore used where higher physical properties are desired to resist pressure or impact or to provide longer service. Whereas in the case of the babbitts, the softer element is the major constituent, so in the bronzes it is the minor constituent. Bearing bronzes are in general, copper-tin matrices filled with lead. The term bronze applies strictly to copper-tin mixture as differentiated from brass—a copper-zinc mixture. These terms are frequently loosely used, and it is quite common to speak of bearings as brasses. On the other hand, manganese bronze, Tobin bronze and a multitude of other so-called bronzes are in reality brasses, to which possibly one or two per cent. tin has been added, and aluminum bronze is usually a mixture of copper and aluminum, sometimes with a small quantity of iron.

NEW USE FOR AEROPLANE

A new use for the aeroplane has been discovered in Canada in carrying out surveys of mosquito-breeding areas. In undertaking such surveys, says Dr. C. Gordon Hewitt, the Dominion entomologist, one is often confronted with the difficulty of mapping out the swamp areas and other breeding places quickly with any degree of accuracy. By means of an aeroplane photographic surveys can readily be made. In forest work also it may be possible to use such a machine for making surveys of timber that is being killed or has already been destroyed by forest insects.

A process is said to have been developed in England for extracting alcohol and its derivatives from coke-oevn gas on a commercial scale. If applied to the whole of the coal carbonised in Britain, the process is estimated to yield 50,000,000 gallons of motor spirit per annum.

Lubrication and Its Importance to Industry

By A. H. NOYES

THIS is truly the age of machinery. The mechanical inventions of the past fifty years have been marvelous. Watching certain modern machines, with their giant arms, manipulating with absolute ease seemingly impossible loads, and watching still another type of modern machine performing operations delicate enough for a woman's fingers, it is almost impossible to refrain from looking for the god, sometimes the demon, who must be hiding behind the machine and working the levers.

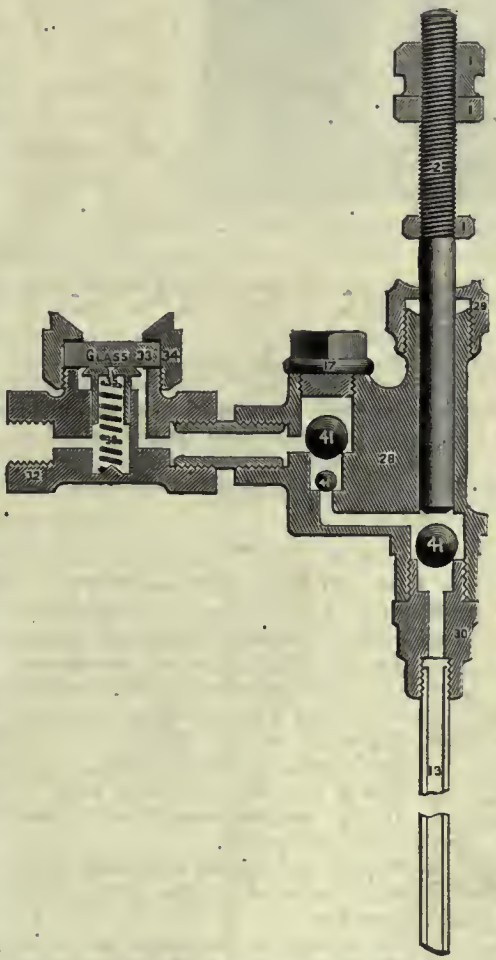
Did you ever stop to think that this intricate and often delicate machinery depends absolutely upon one thing, a thing that can not only stop every current and cog and wheel but damage the whole apparatus beyond repair? Does one person in a thousand realize that this tiny thing, which nevertheless has the life of the whole tremendous mass of machinery in its power, is a drop of oil? What irrevocable damage is caused by two metal surfaces sliding, rolling or grinding over each other, if there is no lubricating substance between.

Ever since machinery has been in existence, lubrication has been its companion. In fact, it existed even before there were machines, when it was simply a case of reducing the power necessary to push one surface over another. People did not know the word friction, did not even know what lubricant meant, but they did know that a little bit of fat or grease made the sliding a lot easier. Even today, in the island of Madeira, the natives' ox-carts have runners instead of wheels, and to assist the patient animal, the driver runs ahead with the "grease rag," with which he smears the cobble stones of the roads. From years of greasing they look like polished ebony.

It is a far call from a wooden sled sliding on cobble stones to two highly polished metal surfaces gliding over each other in a delicate machine, to the powerful piston of a great ship sliding back and forth in the cylinder pushing the whole weight of the ship before it, or the wonderful roller and ball bearings which do so much to reduce friction, and consequently the cost of motive power today. So it is a far call from the grease rag of the Madeira native to the marvelous automatic force feed lubrication of the present day's genius. If the yelling, gesturing native become a bit too tired of running back and forth with his "grease rag" it is only a little more sweat and effort from the patient ox that is at stake, no one hurt, no damage done, only a little more time wasted, and time is a drug on the market with the natives.

But when two polished metal surfaces slide over each other, unoiled, they have a fatal tendency to stick together. Then what? Bearings destroyed, cars delayed, ships at the mercy of wind and wave, time which is worth millions lost, contracts forfeited, and incalculable damage done. Lubrication, then, becomes the sine qua non of industry. This seemingly unimportant thing becomes of prime importance and must be considered from two viewpoints. The first of these is the selection of the lubricant, and the second is the continuous application of this lubricant to the bearings in the amount required.

Only a child would attempt to lubricate the highly polished bearings of an



SECTIONAL VIEW ILLUSTRATING DETAILS OF THE FEEDING MECHANISM.

astronomical instrument with graphite, or to put crude oil in the delicate movements of a watch, neither would highly refined machine oil be of great service in the bearing of a cement crusher. But between these wide limits there is an infinite number of degrees of refinement, and much of the life of a machine depends upon the selection of exactly the right lubricant.

However, the utmost care and the most expert knowledge might be exercised in selecting just the lubricant suited for a machine, and little use would it be if it never reached the bearings. A poor lubricant that reaches the spot is much better than a perfect one that stays in the oil tank. This is where the element of human frailty formerly entered. The man with the oil can was often more important than the president of the company, his mistakes would sometimes be more costly, and both the president and the oiler were liable to error. Men have such excellent "forgetteries." Add to that characteristic the universal tendency to carelessness and to "slighting the job," and you have in humanity a woefully deficient oiling machine.

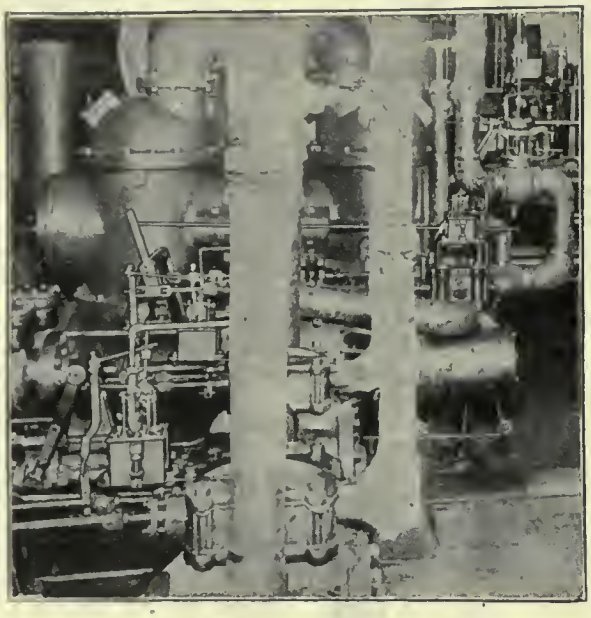
Some accurate and reliable lubricating instrument had, therefore, to be devised. There were, however, certain advantages that the human oiler did have: the machine which should replace him must incorporate all of these advantages to a higher degree, and, in addition, it must not get out of order. So came into existence the force feed lubricator. For instance, the lubricator must start work as soon as the machine starts and must deliver oil in proportion to its needs. A ratchet driven pump was found to best fulfill these two conditions. The motor driven pump of course does not vary its stream of oil and the hydrostatic pump was no more successful. In the latter type the steam condenses in the condensing chamber and forces the oil drop by drop to the bearings. This is successful enough when the machine is working slowly, but when it works rapidly, so much live steam is passing into the chamber that it does not condense fast enough and therefore does not feed the required amount of oil just when the need is greatest.

Hence the ratchet driven pump, to my mind, has almost supplanted other types. It derives its power from a moving part of the machine and consequently stops and starts and accelerates or retards its own speed exactly with the machine. It therefore regulates its delivery in direct proportion to the needs of the machine.

Some of the pumps are fitted with worm gears. These are especially adapted to high speed steam units such as direct connected light engines and sawmill steam feeds of the reversible rotary type. But the "man with the oil can" was not affected by heat or cold, and if working in flying dust he might rub his inflamed eyes, but he still kept on oiling. The best modern force feed lubricators have heaters incorporated in them and they are more oblivious to cold than any man. They do not solidify in winter, therefore, and they do not over-

feed in summer. The only way to avoid dust clogging was to place the oil in a solid box free from the working parts. This principle, as soon as discovered, was applied in the most advanced type of pumps. In this way it was made absolutely impossible for flying dust and grit to get into the oil and be carried to the bearings.

Although accuracy and reliability of action were probably the chief considerations in the mind of the originator of these pumps, yet they have been found to effect a very great economy in oil, as well as in man power. Some of the pumps are credited with saving from 50 per cent. to 80 per cent. of oil—a not insignificant matter in these days; and



THE LUBRICATOR IN SECTION.

The working parts should be as simple as possible and they must be easily reached and repaired. One model has a one-piece valve which eliminates practically all troubles, for it is obviously impossible for a solid casting to get out of order. All the working parts of this model are on the outside of the oil reservoir, which probably accounts for the absence of repair bills for continuous service.

The sight feed is one of the latest and most important devices added to the force feed lubricators. The sight feed leaves the action of the lubricator visible so that an interruption in the flow of the oil is immediately detected. By its means, also, the engineer can see exactly the quantity of oil going to the various bearings.

The lubricators also have several chambers in the oil reservoirs, as many as required, in fact, and can therefore deliver different oils to different bearings. This is necessary to the life of any machine. Pumps of all sizes are in use, from the very small one-feed pump to the one holding several gallons of oil and delivering by forty feeds. The larger pumps or, as they may be called, pump systems are designed for the location they are to occupy. The lubrication of an entire plant is thus controlled from a central point. The economic advantage of such a system is unquestionable. To such an extent is this recognized that practically all the large power plants and all marine engines are equipped with automatic force feed pumps.

the cost of the wage which would have been paid to an oiler doing the work of its forty feeds.

Recent years may have produced more marvelous and more intricate machines than the force feed lubricator, but none to my mind that have demonstrated a greater usefulness or a more perfect adaptation to the needs they were designed to serve.

HOW TO KILL ANY SOCIETY

We often hear how we can help things along, but it remains for the Michigan Architect and Engineer to tell us how we can kill any society or association.

There are ten ways to kill an association, they say, and here they are.

1. Don't come to the meetings.
2. But if you do come, come late.
3. If the weather doesn't suit you, don't think of coming.
4. If you don't attend a meeting, find fault with the work of the officers and other members.
5. Never accept an office, as it is easier to criticize than to do things.
6. Nevertheless, get sore if you are not appointed on a committee, but if you are, do not attend the committee meetings.
7. If asked by the chairman to give your opinion regarding some important matter, tell him you have nothing to say. After the meeting tell everyone how things ought to be done.
8. Do nothing more than is absolutely necessary, but when other members roll up their sleeves and willingly, unselfishly, use their ability to help matters along, howl that the association is run by a clique.
9. Hold back your dues as long as possible, or don't pay at all.
10. Don't bother about getting new members. "Let George do it!"

TAPPING SOFT METALS

In tapping soft metals such as aluminum, there is quite often some difficulty in starting the thread, as the tap will at first either ream out the hole in a partial manner or strip the thread after it is started.

Both these dangers can be avoided, and perhaps the simplest method of all is to make an accurately threaded guide block about the same depth as an ordinary nut.

By placing this guide block in correct position over the hole to be tapped, no trouble will be experienced as the tap must then travel through the soft metal at a predetermined rate. Of course the guide block must be clamped to the work. It is essential that the block be fastened, and another point to be watched is the use of a good lubricant.

Whenever dealing with soft metals, do not rush the job. Humor it, for owing to the weakness of the metal it is likely to break away if too much force is used. Even copper can be stripped if two much force is adopted. If cutting threads on the lathe the danger is not so great but even there it is necessary to use the best of care. Above all see that the cutting tools are sharp. If you don't the results will be far from perfect.

Some recent tests to determine the proper amount of air required for special thermit welding gasoline and compressed air preheaters showed that 25 pounds per square inch seems to be a practical minimum. At this pressure, a single burner preheater will require approximately 25 cubic feet of free air per minute and a double burner preheater approximately 50 cubic feet. For very large welds, where the walls of the molds are thick and the preheater gates longer than usual, a pressure of 40 pounds per square inch would be advisable. This would require approximately 35 cubic feet of free air per minute for a single burner and 70 cubic feet of free per minute for a double burner.

A coating of magnesia cement on the timbers of mines is stated to be an economical and efficient assurance against fire, especially in the arid regions where timber becomes highly inflammable and is difficult to replace. It is elastic, adheres firmly to almost any surface, and is stable and durable.

Have You Tried This Contest Yet? If not--- Do so Now

It's very easy, and at the same time you add to your store of knowledge. The details are given below.

The scale is 6 in. long and is made from finest quality steel. One side is marked in 32nds, the other side in 64ths. A table of decimal equivalents is also stamped on one side, and a table of tap drill sizes on the reverse side. This scale is well worth securing.

What You Have to Do

We publish every week a number of interesting facts or statements selected from the advertising pages for that week. The selections for this issue are given below. Read these through, then turn to the advertising section and see if you can pick out the advertisements to which they refer. The work is interesting, it will train your powers of perception and of memory, it costs you nothing, it will make you better acquainted with the various lines of machinery and tools in the market, and with perseverance you are bound to win one of these useful scales as a prize.

The Prize Winner for December 2nd Issue List is NORMAN POTTS, Monarch Tractors, Ltd., Brantford, Ont. He Had All Answers Correct.

CONTEST FOR DEC. 23RD ISSUE

Contestants are required to write us, stating to which advertisements we refer in this number.

1—Something you can install with your bare hands in five minutes.
2—A discussion about the number of teeth necessary to do different jobs.
3—A product said to be known to the four corners of the world.
4—A product said to drive a certain tool straight and true.
5—A machine that indexes during the return stroke.
6—How to remove stock to a depth of 2 inches, to a limit of .0005".
7—A product that has been made for the last 11 years.
8—A product made by experienced molders.
9—Something said to be the last word in construction.
10—A point that has been emphasized.
11—How to keep your men on the job.
12—How to overcome poor threads and worn-out taps.

These are Correct Answers for List from Dec. 2nd Issue:

1—Federal Engineering Co., Ltd., Toronto, Ont.
2—Geometric Tool Co., New Haven, Conn.
3—Ritchey Supply Co., Toronto, Ont.
4—The Dunbar Brothers Co., Bristol, Conn.
5—The Roelofson Machine & Tool Co., Ltd., Toronto, Ont.
6—Wisconsin Electric Co., Racine, Wis.
7—The United States Electrical Tool Co., Cincinnati, Ohio.
8—Gooley & Edlund, Inc., Cortland, N.Y.
9—The Fisher Motor Co., Ltd., Orillia, Ont.
10—Canada Machinery Corporation, Galt, Ont.
11—Nicholson File Co., Port Hope, Ont.
12—Brown & Sharpe Mfg. Co., Providence, R.I.

Closing Date for This Contest is January 13th

WHAT OUR READERS THINK AND DO

The Design of Hinges and Hinge Pins

A Door Can Be Prevented From Sagging by First of All Determining "Are the Hinge Pins of Sufficient Strength"

By J. S. WATTS

WE have all seen machines of a neat and pleasing appearance spoiled by the doors being loose on their hinges, and hanging at a decided slope when opened, thus giving a worn out, dejected look to an otherwise good looking machine. It would seem that a few minutes of the designer's time, spent in making sure that the hinge pins load, without rapid wear, would be well repaid in the much better appearance of one with one long pin, for comparison. It will be noticed that the two pin arrangement allows the door to sag about twice as much as the one pin design, with the same slack. Moreover the two pin design tends to wear more rapidly than the other.

In the placing of the hinge bars, there are two ways in which these can be placed, as shown in Figures 2 and 3, respectively. If made as in Figure 2, it will be necessary, either to grind or machine the face of the hinge bar to get the door in place, or to leave sufficient clearance to allow for the roughness of the casting. This leaves a gap at "a" which is unsightly and becomes more so with wear. Making the hinges as shown in Figure 3 obviates this difficulty, and the fit becomes better with wear.

To determine the size of hinge pin, etc., is purely a matter of calculating the bearing surface required, as the pin will be of ample strength in other directions if the bearing surface is sufficient.

Referring to Figure 3, the weight acting through its centre of gravity has a leverage "b," while the hinge has a leverage equal to "c." The load "P," on the hinge pins, is therefore

$$P = \frac{W \times b}{c}$$

and if we allow a maximum bearing pressure of seventy pounds per square inch we can expect the bearing to resist wear for a reasonable number of years. The diameter of the pin and the length of the bearing should be about equal to each other.

It is obvious that the greater we can make the length between the hinge bars "c," the lower will be the pressure on the pin, and the less the effect of the wear on the sagging of the door.

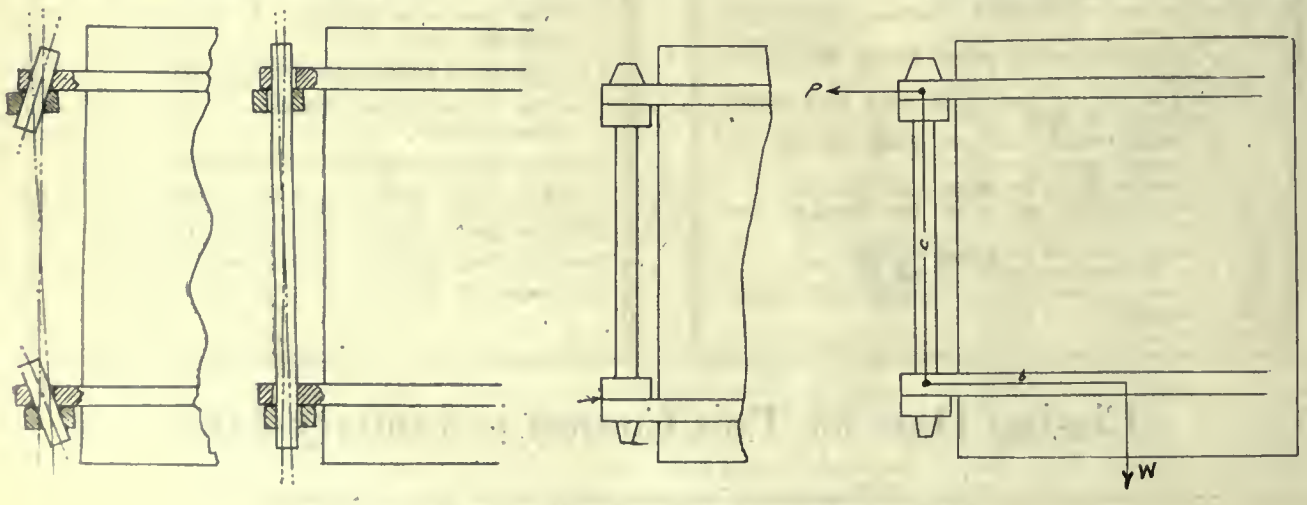
BROACHING ON THE DRILL PRESS

By Harry Moore

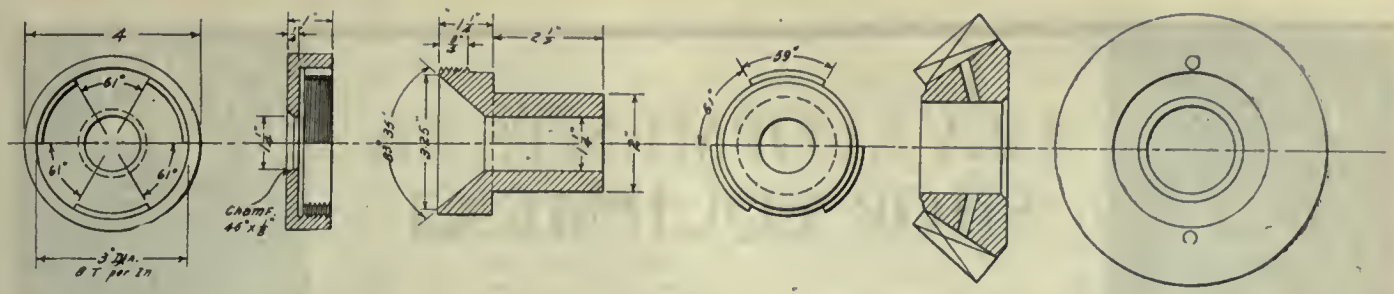
In shops where a limited amount of broaching is done the drill press is very often the broaching machine, and it is the purpose of this article to give some ideas on drill press broaching that may perhaps save many hours of experimenting. Keyways, both single and multiple, form common broaching operations, and therefore will be of interest to many readers. It is always good policy to drill out as much as possible of the keyway to be broached, and this can generally be done if the hole is not too long. In making a jig to drill out the semi-circular grooves, that will afterwards be broached, many mechanics make the bushings as shown at 1, relying on the bushing guiding the drill supported by grooves in the jig itself. This answers very well if only a few pieces are to be made, but the grooves wear out in time, become deeper and out of line, with the result that when the broach follows, it has too much metal to remove, and consequently, the work is not satisfactory.

A better method is shown in Fig. 2, where the bushing is extended to the bottom of the hole. It is a simple matter to replace the bushings when worn. The jig should be laid off and drilled first, then turned to the diameter of the hole in the work; the bushings are made solid and ground away after hardening.

Holding the broaches in drill press spindle is important for obtaining good



FIGS. 1 TO 3—ILLUSTRATING THE PRINCIPLES INVOLVED.



THE VARIOUS DETAILS OF THE CHUCK FOR THE BEVEL PINION.

results. The holder shown in Fig. 3 locates the broach (which is slotted at the top) and holds it lightly in place until it has passed through the work, when the withdrawal of the spindle will release it. The holder is provided with a small pin, behind which is a rubber pad or small spring, which keeps the pin pressed into a groove, thus preventing it dropping out when not in use. Broaching a long hole in the drill press can best be accomplished by using a bar with inserted blades, similar to a boring bar.

Since three or four of these blades will be needed it is essential to have some method of quickly changing them after each cut. The broach bar shown in Fig. 4 is designed with this object in view and answers the purpose admirably, since the only requirement is to keep the cutters central.

Fig. 5 shows the same bar adapted to cut four keyways. It will be noted that the bottom cutter locates the top one, and that by withdrawing the plunger the cutter can be removed, then the top one is free to slide out, providing a quick change; both cutters are slotted at the bottom as shown. The plate screwed to the bottom of the bar is slotted to allow the pin in the plunger to pass through, so that when the plunger is withdrawn it is given a slight turn, which keeps it out of the way while setting or removing the cutters.

It would take too much space to go into details regarding width of teeth, amount of clearance, etc., necessary on a push broach, but a good general rule is—do not try to remove too much stock at the one time, the longer the hole the less metal per tooth, also leave as much chip clearance as possible, for if these get crammed with cuttings before the broach is through, one of two things will happen—either the broach will break, or the path it has traveled since the cramming period will resemble a miniature trench more than a keyway.

The location of the work on the drill press will, of course, depend on the shape of it; simple jigs will nearly always accomplish the end desired. To do quick work, it is better to have both work and broach located, making sure also that spindle is securely locked. Do not allow the broach to fall through the center hole and crash into a soap box on the floor. A better method is to place a block of wood under the table, so that the broach will have only a slight drop after passing through the work. In this way the broach can be replaced in the spindle without sprawling under the table. This may seem obvious to many, but it is remarkable how many instances one comes across in the shope of otherwise well managed concerns, where, with a little thought and effort, a heart or back-breaking job could be transformed into a pleasure.

CHUCK FOR BEVEL PINIONS

By G. Blake

We had a large number of small bevel pinions to grind out in the bore, and as will be seen from the sketch they were not suitable for holding in a 3 or 4 jaw chuck, so the writer got out the special chuck as shown in the accompanying sketch.

The plain part was gripped in the ordinary 3 jaw chuck. The special feature of the idea was the quick handling and loading, which was accomplished by employing the interrupted thread method as is used on the breech block of a gun.

A small groove cut on the cap, and another on the body of the chuck, served as a guide for the operator, so as to enable him to put the cap on in the right place for the thread to engage. Much time was saved in handling the job in this manner and the machine used was a Heald internal grinder.

DEVELOPMENTS IN SHOP EQUIPMENT

OPTICAL MEASURING EQUIPMENT

The Van Keuren Co., 362 Cambridge Street, Boston, Mass., have sent us some interesting data regarding their optical measuring equipment and reference gauges. This optical equipment for the mechanical measurement of gauges by means of light waves is a new development, and is of worthy importance.

Take for example Fig. 1. This view depicts the optical measuring equipment, and this consists of a set of optical glass flats, and a source of monochromatic light, that is, light of one wave length or color.

An optical flat differs from a lens in that it has no magnifying power, but its utility consists solely in that it is a very accurate transparent flat test surface. Working flats 2 inches diameter by ⅝ inch thick are supplied, each having one surface accurately flat within 5 millionths of an inch. Only one of these is required for flatness tests, and the other two suffice for length measurements or comparisons.

One master flat, 2¾ inches in diameter by ⅞ inches thickness, with one surface accurately flat, within 2½ millionths of an inch, serves to complete the set of optical flats. Thus the two working flats and the master, can be proven absolutely by testing them against each other, employing the familiar principle that three surfaces fitting together in all combinations establish or originate flat surfaces. The master flat, in addition to its value for reference purposes, can be used on larger work than the working flats.

Monochromatic Light

The monochromatic light is a most practical arrangement specially designed for every day use. It consists of a conveniently constructed, finished oak box, provided with a tungsten filament lamp and a special selenium diffusing glass. This selenium diffusing glass cuts out all of the wave lengths of the violet, blue, green, yellow and orange light; and transmits only a very definite red wave length, resulting in an equivalent measuring unit of 8 dark interference bands to the ten thousandths of an inch or 12.5 millionths per band. Daylight, which results in merging colored bands with an average equivalent measuring unit of approximately 10 millionths per band is quite satisfactory for flatness tests. The monochromatic light is preferable for flatness tests and is particularly recommended for length measurements. It can be attached immediately to any alternating or direct current lamp socket.

The following rules must be observed when testing for flats:

1. To test a surface by interference bands it must be sufficiently well finished to reflect light. It should be clean and dry; and nicks or feather edges should be removed. The optical flat is then placed on the surface and with a slight pressure manipulated to bring the point of contact to the place desired and the bands a convenient distance apart (usually about ⅛ of an inch).

2. Straight bands indicate a flat surface. Curved bands indicate a curved surface. 3. In testing flatness with daylight, judge the straightness of the bands with reference to the distance between bands of like colors, and use an approximate measuring unit of 10 millionths per band. With the Van Keuren monochromatic light use the dark bands and an equivalent measuring unit of 12.5 millionths per band. 4. When the bands curve one-half the distance between their centre lines the surface is out of flat ½ unit. Other errors are in proportion to the amount of curvature.

5. When the centre of curvature of the bands is on the same side of the bands as the point of contact the surface being tested is convex—when on the opposite side it is concave. 6. The pronounced light spot indicates the point of contact.

7. When comparing two gauges for length as illustrated, they are of the same thickness or length when the bands on both gauges match each other. 8. When a series of straight bands occurs between two flat surfaces, there is al-

FIG. 1—THE OPTICAL MEASURING EQUIPMENT.

FIG. 2—A GROUP OF REFERENCE GAUGES.

ways a wedge of air between them. The bands run at right angles to the direction of the wedge. In comparing two gauges the shorter gauge will have its point of contact lower down on the wedge than the longer gauge, and the number of bands from the point of contact on the shorter gauge to the point of contact on the longer gauge indicates the number of units difference in length.

9. When the bands on two surfaces are parallel, the surfaces themselves are parallel. 10. When a flat gauge is properly wrung on a glass flat it is in contact within about 3 millionths of an inch, and no bands or colors occur.

Reference Gauges

The reference gauges shown on the other illustration are known as set R16. They are specially adapted to departmental and small shop requirements, and consist of five gauges, namely, 1-16 inch, ⅛ inch, ¼ inch, ½ inch, and 1 inch. Using these in various combinations makes available an accurate standard for every 1-16 of an inch. This set is said to be of particular value because it includes the great majority of stock sizes of drills, reamers, plugs, balls, tools, and drawing dimensions.

The flat faces establishing the standard of length are practically true surfaces, both for flatness and parallelism. The maximum variations of one or two millionths of an inch can be detected only with the aid of light waves, the most remarkable and modern measuring facility contributed by science.

A certificate showing the degree of perfection and the actual length measurements in millionths of an inch, compared by means of light waves, with authentic standards certified by the Bureau of Standards, Washington, D.C., is furnished with each set of reference gauges. Each gauge is held within a guaranteed accuracy of 10 millionths of an inch.

The contact face provided on the ⅞ inch diameter reference gauge has an area of .6 square inches. This is from 20 to 40 per cent. larger than usually provided on gauge blocks. A very important fact, however, is that experience has shown that these ⅞ inch diameter gauge blocks wear surprisingly uniformly flat and parallel. This is due to the fact that owing to their circular shape they are always wrung together in a different direction.

Expansion and Contraction

A 1-inch gauge block will expand 0.0000069 inch with a rise of temperature of one degree Fahrenheit. An equal length of iron or steel will expand from 0.0000058 inch to 0.0000072 inch depending upon the character of the material.

Thus, a tool or part made in accordance with these gauges, when the temperature is 80 degrees or 50 degrees, will contract or expand as the case may be almost the exact amount to bring the part being made correct at 68 degrees Fahrenheit, the standard temperature of measurement.

This automatic temperature control is of fundamental importance, for without it great difficulties would result.

TWO SPINDLE DRILL

The Black & Decker Mfg. Co., of Towson Heights, Baltimore, Md., has recently designed a two-spindle drill, specifically adapted for drilling holes necessary for the Murphy top fastener. This fastener is used for attaching automobile side curtains and when the base of the fastener is put on the automobile body, two holes ⅞ inch apart are necessary. This new machine drills these two holes the correct distance apart in the same operation.

The handle of the drill is like an automatic pistol and a pull on the trigger sets the two drill bits in motion. A second pull stops the drill and in this way the operator can control the tool without changing the position of either hand. The motor and the gear construction necessary for driving the two spindles is simple but rugged. The gears themselves are of the finest grade steel, heat treated. The two spindles have specially designed chucks to hold the two ⅛ inch drill bits.

GENERAL VIEW OF TWO-SPINDLE DRILL.

The tool is exceptionally light and by holding it in the natural way with the forefinger on the trigger the operator is able to drill two holes at the same time ⅛ inch in diameter and ⅞ inch apart.

COMBINATION DRILL AND REAMER

A tool that has been specially designed for use on jig work has been brought out by the Fastfeed Drill and Tool Company of New York City. This is a combination drill and reamer made of high-speed steel. The drill size is made about .010 to .015 inch below that of the reamer which is the desired size of the hole. The tool has four blades and they may be sharpened on the front edge as in the ordinary reamer. It is claimed that a high rate of production can be maintained with these tools. These tools can be obtained with shanks to fit any existing equipment.

SURFACE GRINDER

The Perfect Machine Co., Galt, Ont., have placed on the market a new surface grinder. This machine has a vertical travel of 8 inches, and is equipped with a table 18 inches by 8 inches, having a micrometer adjustment. The machine will take a 12-inch by 2-inch emery wheel, and is suitable for all kinds of surface grinding work.

They are also manufacturing a new 20-inch light type drill press that is equipped with both gear and power feed.

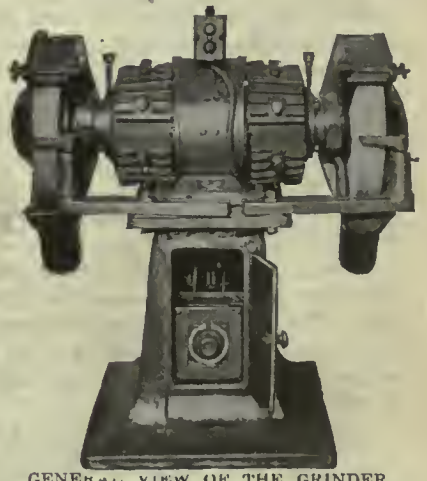
STRAIGHT-COLUMN INCLINABLE PRESS

Several interesting features are included in the recently designed straight side press brought out by the Toledo Machine and Tool Company of Toledo, Ohio. The press is direct motor driven and the motor pinion is always in mesh no matter what the inclination of the press. A special elevating screw is provided at the rear of the press for angular adjustment. The press may be furnished with or without gearing or other auxiliary equipment, and the frame may be designed to permit side feeding of the stock.

SELF-CONTAINED GRINDING MACHINE

The U. S. Tool Co., Cincinnati, Ohio, has recently placed on the market the self-contained tool-grinding machine shown in the illustration, ease of starting and total enclosure of the motor and control apparatus being features claimed by the maker.

The machine is equipped with a 5 h.p. shunt-wound, adjustable-speed Westinghouse motor running at from 1,120 to 1,600 r.p.m. on 230-volt direct current. The motor is started and stopped by a push button that controls a type C Westinghouse starter equipped with a speed-adjusting rheostat and located in the base of the machine. The push button is mounted on the top of the motor so that the workmen will not start the motor by jabbing the button with the material which they intend to grind, since it is easier to operate it by hand.



GENERAL VIEW OF THE GRINDER.

A Christmas Message

CANADIAN MACHINERY extends to its readers its best wishes for a Merry Christmas.

"Just another year, another link,
To bind our friendship closer."

In this money-mad age we are apt to forget at times the real motive behind Christmas giving. It is a fact that a great section of the world has been so busy with grabbing and getting that it has had little time to pay much attention to the development of those finer traits that find expression in giving, and in considering the happiness and comfort of others.

It may clash with the teachings of certain radicals, both in the ranks of employers and employees, that it is a more wonderful thing to give than it is to receive. Despite this, that great old truth has stood for centuries and it will be here long after all the radicals, money-grabbers, agitators and the get-rich-quick group have passed on and been forgotten.

Christmas, 1920, finds the world rid of nearly all its war—finds nations, after months of skirmishing, still seriously considering the best way to weed out the chances of future wars through a combination of their resources and energies.

Things have not gone to the dogs, though there have been enough adverse currents to force them in that direction. The general bulk of business in this good land is still sweet and wholesome and showing signs that it is ready to sprout and grow into bigger and greater things in 1921.

To the advertisers in Canadian Machinery—we have appreciated your confidence during the year in our ability to carry your message to the industries of Canada and to distant parts of the Empire. We have tried to merit this appreciation by producing a paper that is sold to the readers on its merits, without premiums and without any inducement other than its educational and business value to the subscriber.

And so may your Christmas be a happy event, filled with kind deeds and inspiring thoughts, crowned with love and enriched with the sense and satisfaction of duty well performed and days profitably invested.

The Luxury Tax Off

THE removal of the Luxury Tax should help the machine tool business and many kindred fields indirectly. There has been so much tinkering with business in this country that the wonder is it has survived at all. Buying and selling, losing and making, have been twisted and bent out of form entirely, until one is forced to the conclusion that the more Government officials keep their hands off business in general the better for all concerned, especially for sound business itself.

The Luxury Tax did not directly touch the iron, steel and machine tool business, but it did touch the automobile business, and that is coming pretty close to the former, and it did touch many other lines, the stopping of which backed up on the tool and steel business in short order.

The machinery, iron, steel and metal working industries in this country need all the assistance they can get right now. They are buying from an admittedly high market and they are taking chances on selling into one equally as good as far as recovering their investment is concerned.

The manufacturer who is going ahead and doing his best to provide as much employment as possible is performing a far greater service than the class who are tub-thumping for tariff removals and decrying the importance of the manufacturer to the community.

Is This a Fair Practice?

OTTAWA reports indicate that complaints are still coming in that "freights on Canadian goods shipped from Canadian ports to Britain on Canadian lines are demanded in American instead of Canadian dollars. The Canadian Government Merchant Marine," continues the despatch, "has written to the Commissioner of Commerce that they have always made their freight collections in Canadian dollars. The complaints from Great Britain continue in regard to the practice of other lines demanding American dollars for Canadian service."

The report that the Canadian service never asks for payment in New York funds may be quite correct as far as present practice is concerned, but there are cases on record where it has been demanded, and bills of lading to this effect have been forwarded to the Department at Ottawa. Trade commissioners in various parts of the Old Land have complained several times about this practice.

Canadians are hurting their connections abroad by trying to nip in on American exchange when they have no right to do it.

If it is a Canadian product, shipped on a Canadian line to a country that is in no way connected with United States, it is hard to dig up a good excuse for adding a line to the effect that payment must be made in New York funds.

It is a short-sighted policy, and one that looks long and hard at a little present gain, rather than on developing and building for the future a trade that is going to continue to come back with its repeat orders in days when the business may be badly wanted.

MARKET DEVELOPMENTS

All the Markets Have Had A Quiet Week

Prices, Say Machine-Tool Builders, Are Not Going to Come Down as Costs are Still Up—Many Independent Mills Are Now Down for Lack of Orders—Carbon Drills are Marked Down.

DEALERS state that this time of the year should be rather dull even in normal times, and the machine tool trade will admit that these predictions are being fulfilled in this district. Nor is there any isolation in regard to the condition, New York reporting conditions much the same as here. The New York market is getting the worst of it from the standpoint of the dealers as a number of tools are being put out there for resale at figures well below lists. Yet the makers of machinery do not seem to be in the mood to be stampeded, as only this week several of them sent letters to their representatives in Canada that they were not making any changes in their selling prices. Their costs of production were not easing off, and that was the basis on which they were working, hence they could make no better selling prices than those already authorized. That, in brief, was the drift of the announcements.

Steel warehouses are quieter than they have been for some weeks past, although some of them claim a fairly good volume of trade. This may be accounted for in part by the fact that manufacturers prefer to draw from warehouse stocks rather than make up a mill tonnage themselves. So the warehouse trade cannot always be looked upon as a reliable barometer of business conditions.

Boiler tubes head the list of good sellers during this season. Most of the lake fleets are tied up now, and work starts at once on going over the equipment. Stocks are in good shape to supply all sorts of needs for this work, much better, in fact, than they have been for many months past.

Carbon drills were brought down by Canadian makers during the past week. They have been selling at 35 per cent. off the list, while the new price is 40 and 5 off.

The scrap market does not improve, nor do dealers see where any improvement is coming from. They refuse to buy except to fill contracts, stating that for the present they are out of the market.

MONTREAL GETTING IN SHAPE FOR THE DEVELOPMENTS OF 1921

Special to CANADIAN MACHINERY.

MONTREAL, December 23. — While here and there one hears the remark that business is good, the general impression is that quietness prevails, but of a character that would imply "the lull before the storm." The magnitude of the aftermath may be of small proportions, but the opinion is general that early in the New Year we will experience a partial return to more active participation on all sides in the development of industry and commercial activity. The C. P. R. management are taking advantage of the slack period and are closing the Angus shops for about two weeks, for the purpose of generally overhauling the plant and equipment. This is only one of the many instances where factory operations are being temporarily suspended to take inventory and make necessary repairs. In no small degree this has been reflected in the decline that has been noted in other lines of the metal industry.

Steel Movement Very Quiet

The steel situation continues to move along in the listless manner that has marked its movement for several weeks past, with such sufficient business passing to maintain the interest of dealers and producers, the consumers invariably being a passive spectator as to iron and steel activity. This does not mean that buyers are completely out of the market, but that their needs are gauged by the general requirements, and these have been materially reduced during recent weeks owing to the conservative policy that has been adopted on all sides. "The volume of business at the present time," remarked a dealer here, "is not of an encouraging character, but when conditions are taken into consideration, it is not surprising that this falling off in demand has developed. We are able now to get shipments from the mills almost as soon as the order is turned in, and, as a matter of fact, material previously on order is coming through in such quantities that our warehouse is beginning to take on a well stocked appearance. Some of this has been laid down at fairly high figures, while later quantities are coming in at more reasonable prices, so that in making sales we are able to equalize on material on hand. We are expecting some slight adjustment on some lines, as black sheets and plates, but believe that prices in general will hold comparatively firm."

Stock Taking Affecting Business

The fact that many industrial plants reserve the closing month of the year for their periodical stock taking has reacted on the business carried on, not alone in the plants directly affected, but also in other lines of activity that depend on co-operative enterprise for equalization of trade. Some shops throughout this district are taking this opportunity to readjust their operating staffs, and take a more than usual interest in the inventory of shop and equipment. "During the past week," stated one machinery dealer, "our representatives have been brought in touch with the stock taking phase of industry, where plants are practically closed to the outside world, as regards the purchase of material other than that required for absolute necessities. In some instances we are told that closing down is contemplated, for varying periods, for the purpose of taking stock and general readjustment of

working conditions. This attitude is the feature of present conditions and for the next few weeks will probably be the chief factor in industrial activity, or rather the lack of it." Asked as to the outlook for 1921, the dealer stated that he had every hope of a good year, slow at first but accelerating in the early spring. "With the gradual resumption of activity, which we anticipate early in the year, we may see a readjustment of prices, based on the new order of things as developed out of revised production costs, chief of which will be labor."

Buying at Low Ebb

The situation in old materials is still one where the interest of the dealer is hard to arouse. The consuming trade is almost nil and dealers are reluctant to take on any additional supplies in the hope of making a later sale. Present business is largely of the hand-to-mouth variety, where a direct transfer is made from seller to the buyer, through the dealer. Some light business is carried on regularly in meeting the needs of local foundries, but nothing of a special character has featured the scrap market for some time. "We are more than ordinarily quiet for this time of the year," said a dealer, "and we lay this to the readjustment that is taking place in many of the industrial plants throughout the country. Until this phase of industry has become more settled we are not looking for a renewal of active buying of scrap." Asked as to the possible duration of the slack period, the dealer would not commit himself, but the impression gathered was that before February there would likely be a gradual return to more active operations. In the absence of any marked movement of old materials dealers are satisfied to let quotations stand, as prices can only be based on individual sales. However, those quoted are the nominal average for the current week.

TRADE IS QUIET IN THIS DISTRICT

Makers Say They Are Not Changing Their Prices—Carbon Drills Are On a New Schedule

TORONTO.—If the removal of the luxury tax affects the machine tool business it will be in a reflex way, and will not be apparent for some time yet. The machine tool field is essentially in the class of essentials, and has not felt the tax as directly as many other lines. At the same time the removing of anything that will change the mental attitude of the buyer toward coming into the market to make purchases is going to work out to the good of trade in general.

Makers have not budged recently in the matter of prices. Such announcements as were going to be made came out some weeks ago, and since then the other makers have done nothing at all toward revising the selling schedules on which they are working. This morning one of the dealers showed this paper a letter which he had received from one of his principals, in which it was stated plainly that they had made no reduction in price, and were not contemplating making any reduction. The letter went on to point out that labor was not down yet, and there was no lessening of the cost of production or of carrying costs. This firm held that it would be a serious thing for the company to go out and make a cut in the price now. The dealer who received the letter said he was not particularly anxious to have any reduction made at this time. He was quite satisfied that were he to start out today with a reduced list on his lines he could not use it to advantage. That feeling seems to be general, although one of the Toronto men in the machine tool business remarked this morning that it had often been the case, in his experience, when there was considerable talk about there being no drop in prices, the change came.

Hard to Sell Here?

"It is a hard market in which to sell machine tools on the basis of performance," was the complaint of one dealer this morning. "I may be wrong in the firms I work with, but in many cases I find that after going thoroughly into the working details with a man who is interested in a machine tool, and showing him where he will be money ahead every day by putting in the new equipment, he will buy a machine for less money. Many of the firms talk about going in for export trade, but I believe that they will have to manufacture to better advantage before they ever make much of a success in this line. It is one of the most discouraging things a machine tool salesman can run into, viz., trying to sell on a good sound basis, only to find that you lose ground many times by following this method."

A Quiet Month in Warehouses

Warehouse trade in steel business is quiet this month. It is in almost any year, and dealers are not prepared to state what percentage of their lessened trade can be blamed to seasonable conditions. It used to be said that steel was a good market barometer, but there are some exceptions, and the warehouse business is one of them, in that it may be very good while industry in general may be very quiet. Right now there are quite a number of firms in the country that are not buying for stock but drawing on the warehouses instead. This brings quite a bit of trading to the warehouse, but it does not mean that any more goods are being turned out, because the manufacturer in many cases would rather buy in small lots from the warehouse than make up a tonnage good enough to be forwarded to the mills in the ordinary way. Thus mills and factories may be operating at a very small percentage of their capacity and the warehouses may be quite busy supplying business that does not come to them at all when these same customers

POINTS IN WEEK'S MARKETING NOTES

The machine tool market in New York continues to be remarkably dull, and a number of makers are closing down their plants for the holiday season.

—

Many new machine tools are being offered by the United States manufacturers at a reduction from list prices. They have bought more equipment than they see use for now and are anxious to get rid of it even at a loss.

—

The price of carbon drills has been reduced in Canada. The old price was 35 per cent. off the list, while now the selling price is 40 and 5 off.

—

Some machinery dealers in this district have received word from their principals during the past week that they have no intention of reducing prices, as their costs are still too high to permit of any such action.

—

The steel warehouses are still doing a fair amount of business, as many manufacturers prefer to draw from the stocks in these places, for actual wants rather than to make up a mill tonnage under present conditions.

—

Boiler tubes are the bright spot in the steel market just now, as many of the lake fleets are tying up for the season and will immediately undergo repairs.

—

The scrap metal market is exactly where it was a week ago. Dealers in this district are refusing to buy except against contracts.

—

Pittsburgh reports state that a number of the smaller independent mills are closed entirely, and that the operating average of them all is not much over 35 per cent. of capacity.

—

Some reports have it that one of the next developments will see the independents cutting the Corporation prices.

—

There is very little business being done in pig iron at any of the furnaces, and reports from blast furnace centers indicate that some of the stacks are blowing out.

are busy enough to warrant them placing mill tonnages for building up their own stocks.

Canadian warehousemen, it is claimed, cannot make as much on their turnover as the warehouses in United States. By the time the steel is laid down here they are up against a much higher cost than the U. S. warehouse and cannot recover proportionately as large an amount from the consumer.

Yards Not Busy Now

Apparently many of the warehouses are finding difficulty in keeping their men busy in the yards and shipping departments. There is not the volume of business moving there was a few months ago, although up to date there have been very few cases where men have been let out. A number of the dealers mentioned this and the chances are that some action may be taken toward making a reduction in hours or days of employment until there is some improvement.

Tubes are the brightest spot in the business now. Fleets are tying up for the winter at a good many of the lake ports, and that replacement and repair business is starting to come in nicely now. There is a good assortment of tubes on hand, much better than several months ago, when it was a difficult matter to keep all the wanted sizes in stock.

Carbon Drills Down a Little

A change was made in the selling price of carbon drills, the new price becoming effective the 20th of the month. These have been selling at 35% off the list for some time now, but the new price is 40 and 5 off. It works out about like this. Take a one-inch drill which is listed at $3.50, with 35 off would mean a price of $2.28 to the buyer. Now it will mean with 40 and 5 off, a price of $2 to the user. All the Canadian makers have adopted the new price.

There is a fair amount of "pick-up" business going now, but the average order is not very large. The National Railways have a requisition out now for some small tools.

No Improvement Here

The scrap metal market is just where it was last week. There is only contract dealing going on, and that is in very limited volume. The yards are still very much disinclined to take on any material and they are assuming the same attitude as formerly, viz., that they are absolutely out of the market, and they want it clearly understood that any prices they are responsible for quoting in print are purely nominal.

THE INDEPENDENTS MAY CUT THE PRICE IN EFFORT TO GET ORDERS

Special to CANADIAN MACHINERY.

PITTSBURG, December 23.—There has been a still more impressive decrease in the operations of the independent steel interests. One large independent is reported to be operating only three of its twelve blast furnaces, with steel making departments slowed down almost as much. Not a few of the smaller mills are closed entirely. The operating rate for the independents as a whole probably does not average over 35 per cent. and the common prediction is that by the first week in January the independents will be down to practically nothing.

This condition does not indicate that steel consumption has ceased by any means, for the United States Steel Corporation, instead of making less steel than formerly, is making more. The corporation is operating 91 per cent. of its steel ingot capacity, against 88 per cent. two or three weeks ago. It is not on account of increased pressure upon it for deliveries that the corporation has lately increased its production, but because it can now do so. For more than a year the corporation has been endeavoring to produce all the steel possible, and lately, with the loosening up of the trade situation, it has better supplies of coal and coke whereby it has been enabled to blow in some blast furnaces that had been idle perforce.

When the Steel Corporation operates at 91 per cent. of capacity, which is approximately 23,000,000 gross tons a year, it is producing at the rate of 21,000,000 tons a year. During the first ten months of this year production by the industry as a whole averaged a rate of 42,000,000 tons a year, there being only relatively minor variations, in individual months, from this rate. Thus the Steel Corporation is now producing one-half as much steel as was formerly produced by the whole industry. Beyond question the consumption of steel has greatly decreased, and thus there is left little business for the independents. It is not a case of the Steel Corporation taking business away from the independents, but one of the corporation having previously booked the business, when the independents were charging high prices and buyers would patronize them only for early deliveries. Many consumers were buying both from the corporation and from independents and now, with reduced requirements, they can get along with their Steel Corporation deliveries.

There is an interesting aspect to this alignment. For years there has been a question whether or not the Steel Corporation is a "trust." In the suit of the Government, the Supreme Court decided in favor of the corporation, but by a narrow margin, and the matter was left in such shape that if the corporation should alter its policy there would be ground for re-opening the case. It has been quite a common view that the Steel Corporation should keep its proportion of the total capacity under 50 per cent. The corporation is on the safe side in that, for at the outside, its capacity, measured by steel ingots, is only 44 per cent. of the total. Obviously there can be no harm in the corporation making more steel than its "proportion" if it does so by letting the public have the steel at lower prices than the independents ask. Last year the corporation made 51 per cent. of the steel, instead of 44 per cent., this year there will be something of the same sort, and if present conditions continue any length of time the corporation will show a very high percentage of next year's production. Nobody could complain about that unless it would be the independents, and they would hardly be able to find a point of law on which to hang such a complaint.

Strip Steel Lower

The mills have made additional reductions in strip steel, following those of a fortnight ago. At that time the nominal prices were 5c for hot rolled and 8c for cold rolled, but the open market as shown by a few sales was half a cent less. The reduction was to 4c and 7c, respectively. The present reduction is to 3.30c for hot rolled and 6.25c for cold rolled. Strip steel had scored much heavier advances than other rolled steel products, except sheets, the reason no doubt being that the automobile industry played such a large part, and the automobile factories were quite reckless earlier in the year in bidding for steel. The new prices, however, are really in keeping with the general steel schedule. The 3.30c price for hot rolled strip steel is simply the standard price of 3.05c for hoops, plus an extra or advance of 25 cents per 100 pounds for the quality, including accuracy, surface finish and stamping quality. Under the war control there were two extras, one of 25 cents per 100 pounds, over the hoop and band base price of 3.50c for "stamping quality," and one of 50 cents for "deep stamping quality." Now no distinction is made, all hoops being regarded as "deep stamping," and the material is simply called hot rolled strip at 3.30c instead of 3.05c, base, plus 25c extra for stamping quality.

Steel Prices Steady

At various times recently the independent market on tin plate, bars, shapes, plates, wire products and sheets declined to the Steel Corporation level. Pipe did not decline, and has not declined to date, the independent list being $7 to $10 a ton above the Steel Corporation prices, these being on a list with a basing discount of 57½ per cent. As the independent pipe mills have been receiving lately a few cancellations and a great many postponements or suspensions they will probably have to drop within a short time.

In the commodities in which the independent market has declined to the Steel Corporation level, no important shading has as yet appeared, although it is a common expectation that in due course some of the independents will cut the corporation prices. There is, of course, some quoting by western mills that technically represent price cutting, but the common view of this is that it is simply an ignoring of the "Pittsburg base," mills naming delivered prices that represent less than the regular Pittsburgh price, plus rail freight from Pittsburgh to destination, but a higher net price f. o. b. the mill than the Pittsburgh price. Particularly with the advanced freight rates in effect since August 26 there is a natural disposition, when orders are scarce, for the removed mills to ignore the Pittsburgh base.

The pig iron market remains stagnant. Nominal prices remain: Bessemer, 35c; basic, $33; foundry, $35, f.o.b. valley furnaces, freight to Pittsburgh being $1.96. There is no incentive to furnaces to reduce these prices as there is no inquiry, hence no opportunity for competition. Next month will probably see some declines, possibly to $30 for basic and foundry and $32 for Bessemer, but there may not be enough furnaces in blast for any actual reductions to occur. Only a third or a fourth of the valley merchant furnaces are now in blast, and these may not stay in.

While furnaces in general have been indisposed to contract for Connellsville coke for the half year, feeling that they do not know whether they are going to run and that the coke operators are not yet down to their lowest terms, a fair amount of business has gone through in the past week or two, involving perhaps 75,000 tons a month, but of course on a "requirement" basis, so that if the furnaces do not run they are under no obligations. All the business was closed on a ratio of 5 to 1 against basic pig iron at valley furnaces. If basic iron, now $33, is $30, something not at all improbable, the coke will be invoiced at $6 month by month until there is a change in pig iron. The contracts generally have a minimum below which coke cannot go, irrespective of pig iron, and some at least provide for a stiffer ratio in case pig iron advances above a certain point.

Spot coke is $5.50 to $6 for furnace, and $7 to $7.50 for foundry, per net ton at ovens, Connellsville region, though some particularly well known brands of foundry coke command more. Three important producers of foundry coke are quoting on first half contracts $10, $9 and $8.50, respectively, but none of them is booking any business of consequence.

NEW YORK HAS A VERY QUIET WEEK

And Tool Makers are not Likely to Operate Their Plants at Full Capacity

Special to CANADIAN MACHINERY.

NEW YORK, December 23.—The year is drawing to a close with no improvement in the machine-tool business, but eyes are eagerly turned toward the new year, when at least a modicum of betterment is expected. Some in the trade are not sanguine that there will be any marked increase in sales for several months, but it does not seem possible that conditions as dull as those which have prevailed during November and December can continue for long. December sales of some concerns in the trade scarcely provide for postage stamps.

New machine-tools are appearing on the market in increasing numbers and must be absorbed before there is substantial buying from the manufacturers. Many of the tools are being offered at sacrifice prices. A large company has placed on sale about 125 standard machines, many of which have never been removed from shipping crates, and at prices about 25 per cent. below those today quoted by the makers. Some companies overbought and are now anxious to dispose of their surplus equipment, even at a loss.

Most machine-tool plants will operate at a low rate over the holiday period and some will shut down entirely for a week or more.

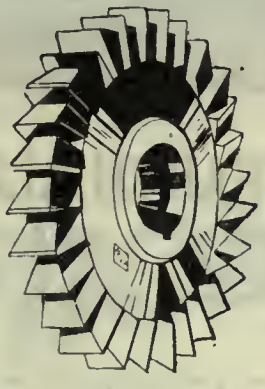
WILT

"Where there's a WILT—there's the Way."

High Speed and Carbon Twist Drills, Reamers and Milling Cutters



Ask your dealer or write direct for Catalog "C."

The Standard of Quality

How many times have you heard that some other tools "are as good as Wilt"? There must be, and is, a reason for this expression. Do you ever think of it? The merchant selling the other tools recognizes the quality of Wilt and therefore compares those which he sells with tools whose merit is well-known.

The next time anyone says a tool is "as good as Wilt," consider why he makes the statement.

THE JOHNSON FRICTION CLUTCH

Johnson Clutch Installation on a Newton Milling Machine

Clutches for Reversing Functions

A reversing clutch is a very common requirement on machinery, and one which is encountered in many different forms. Whatever the situation may be, a Johnson Clutch offers the best method of handling it.

The bevel gear assembly shown here is one of the ways in which a Johnson Double Clutch is frequently applied for reversing functions. Many of the best machine tools are equipped in this manner.

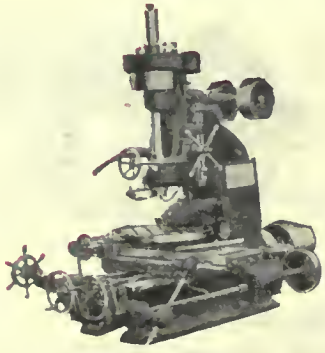
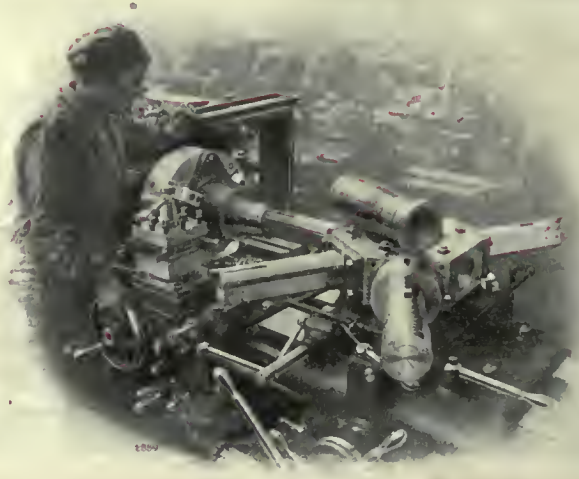
ALFRED

1-3 JARVIS STREET



Horizontal and Vertical Milling Machines, manufactured in a range of sizes.



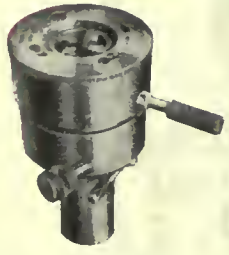
MACHINE TOOLS

THE machine tools included in the equipment of a modern engineering works may be roughly divided into two classes—main and auxiliary. Whilst the character of the former will vary with the nature of the work, the latter are, generally speaking, the same throughout the entire industry.

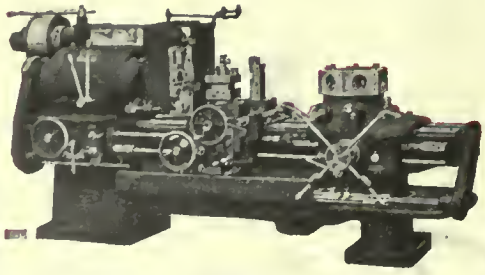
Thus the main plant of an automobile factory will consist largely of full and semi-automatic turret lathes, milling machines, gear cutting machines and grinding machines, which are used only to a comparatively small extent in a marine engine shop.

The auxiliary plant, however, will be much the same in both establishments; cutting-off machines, tool, cutter and twist drill grinding machines, universal milling machines, tool-room lathes and universal grinders being necessary in some degree to all metal working undertakings.

For the last 25 years both main and auxiliary plant have been supplied by this firm for every kind of engineering work produced by machine tools.



The Coventry Self-Opening Die Head, made in seven sizes—5-16" to 3".



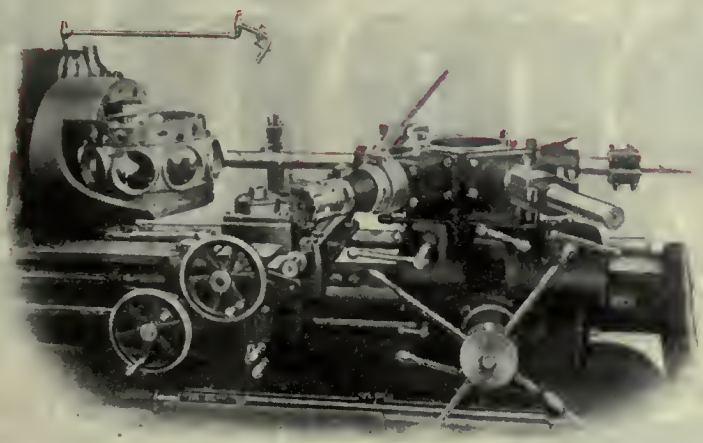
Combination Turret Lathes, made in five sizes—13" to 28" swing.

HEAD WORKS:

COVENTRY, ENGLAND

HERBERT

TORONTO, ONTARIO *LIMITED*



The Coventry Concentric Chuck, made in six sizes, 9" to 25".

OF QUALITY

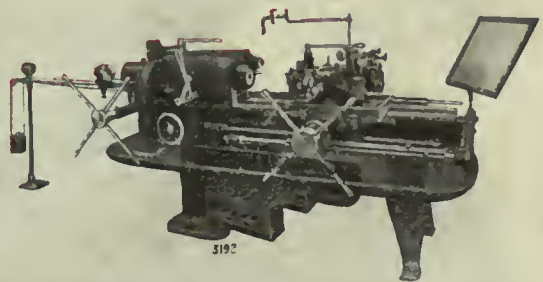
THE manufacturing energies have been principally devoted to the development of a line of labour-saving machine tools used for repetition work. Turret lathes, capstan lathes, auto lathes and full automatic screw machines have always been a specialty. These machines are offered fully equipped with all the special tools and fixtures necessary for producing any specified work and at the same time guarantees of production can be given; these form a reliable basis on which labour cost of the work can be estimated.

A variety of both auxiliary and general purpose machines, comprising universal tool and cutter grinders, twist drill grinders, horizontal and vertical milling machines, ball-bearing drills, precision screw lathes and measuring machines are also produced.

In addition, sole selling agencies are held for the products of many prominent British and American firms. A comprehensive range of both machine tools and small tools can thus be offered which adequately fills the requirements of the modern machine shop.

Branches and Associate Companies at:
Toronto, New York, Paris, Lyons, Lille, Brussels, Milan, Calcutta, Bombay, Yokohama, Sydney, Etc.

Ball-Bearing Drilling Machines, made with one to four spindles.

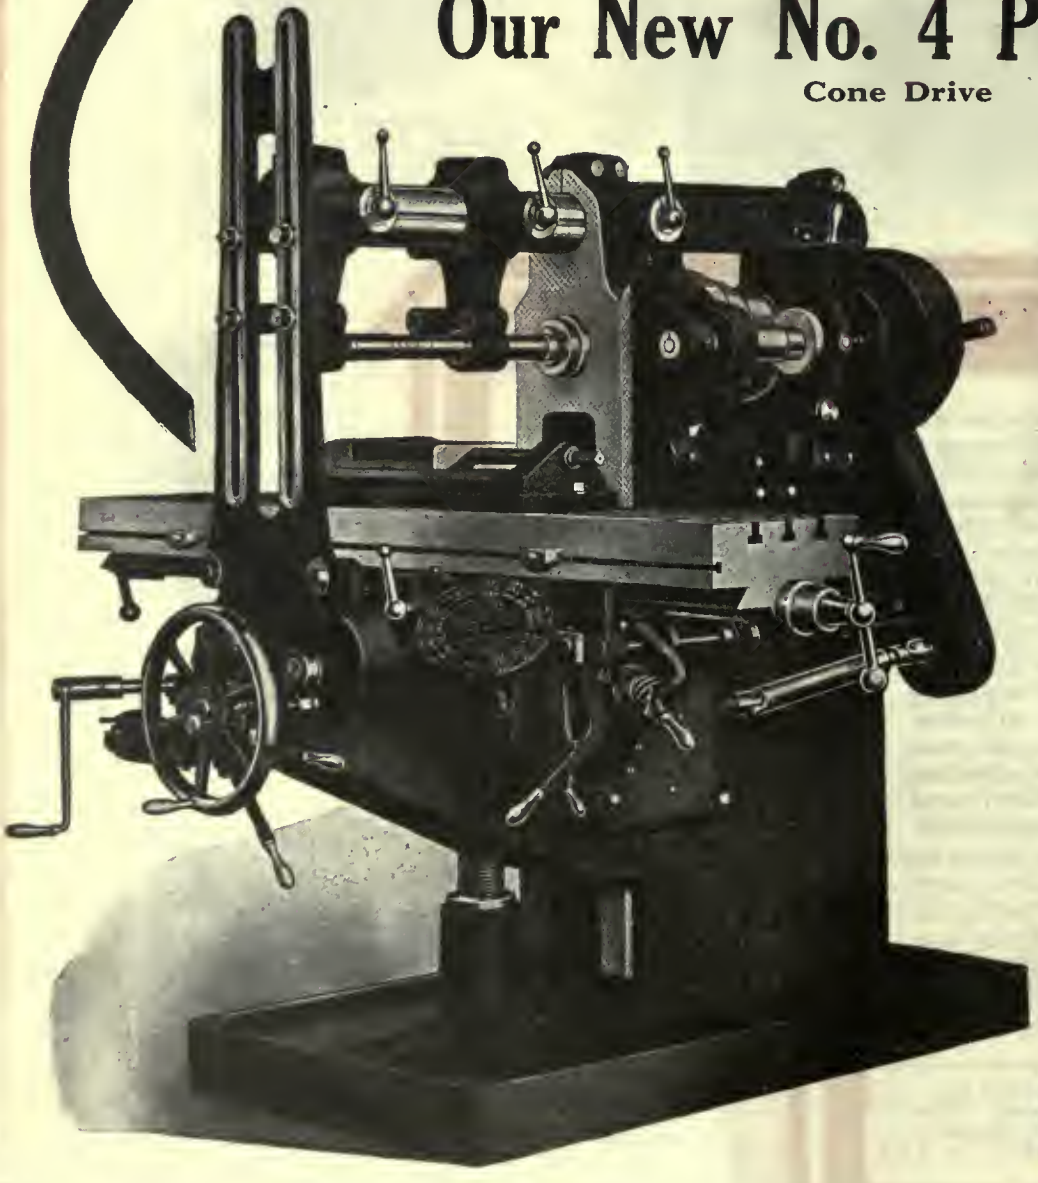


Hexagon Turret Lathes for bar work, made in three sizes for bars up to 1⅝", 2¾" and 3" diameter.

Ford-Smith

Our New No. 4 Plain Miller

Cone Drive



THIS machine may be aptly termed "the last word" in high-grade Millers. Its design includes the very latest developments to promote convenience, speed and accuracy, all of which tends to cut the cost of production in the shop.

In this new No. 4 special attention has been given to centralized control of all movements of the knee and table. Rapid power is provided in all directions and this feature, in combination with centralized control from the operator's working position at the front of the knee, makes for rapid production in all classes of work. The extreme range and coarse feeds are equal to those provided on all-geared millers.

We can hardly do justice here to the fine points of this excellent machine tool in the apace we have at our disposal. Write for full description.

WILLIAMS

PIPE MACHINES

Used Throughout Canada and British Empire

THE Williams Tool Corporation of Canada, Limited, has taken over the business of John H. Hall & Sons, Limited, Brantford, Ont., and will continue to make the Pipe Machines that made the name of "Hall" favorably known throughout Canada and the British Empire. The new company will maintain the "Hall" standard of **quality** and **service,** and will combine the features of the "Hall" and "Williams" products with the aim of keeping them the best on the market.

A Few Outstanding Features

1—Single Pulley Drive, through.
2—Dodge Friction Clutch, on machine.
3—Clutch Lever at operator's left hand.
4—Rigid Bearing Bracket on drive shaft.
5—Gear Box Drive away from operator.
6—Individual Adjustment for each bearing.
7—Large Spindle Bearings are ring oiling.
8—Compact Control Levers on operator's side.
9—Large Die Cabinet and Tool Tray.
10—Substantial Oil Trough around top of ways.
11—Specially conatructed Reservoir and Filterer.
12—Low-down Sliding Head.
13—Rotary Geared Pump reverasible for left-hand thread.
14—Specially designed Carriage to drain off oil and cuttings.
15—All Gears amply protected.

Movements

On your production problems consider the automatic movements—an automatic way to success.

These machines have been developed so that an operator will be able to handle more than one machine, and regarding accuracy, ease of setting up the work for different operations, and mechanical construction that gives long service and keeps repairs and replacements down to a minimum the P. & J. has a record that will be doubly interesting to you.

We have shown in previous issues how the P. & J. multiplies production—how one man can run from 2 to 6 machines—how the highest standards of accuracy are met, and how costs are lowered to a low point.

But if you want to see how easy it is to set up and adjust the P. & J.'s for different jobs—you ought to visit some of the plants where they employ batteries of these machines.

Write us and we can tell you where to go to get this first hand performance proof on work like yours.

OIL-HARDENING NON-SHRINKING

HALCOMB "KETOS" TOOL STEEL OIL-HARDENING NON-SHRINKING

You'd Hardly Believe This Possible!

—but Facts are Facts:

THE two dies shown above are made from Ketos Steel. The new die shown to the left is 1¼" thick, the used die shown to the right is only ⅛" thick, yet it produces blanks of accuracy equal to the new one.

The used die has produced over 1,000,000 armature punchings for the Robbins & Myers Co., Ltd., Brantford, Ontario, and has been ground between 60 and 70 times.

It takes a die-maker to thoroughly appreciate this statement, and this example only proves what we have always claimed, namely, that the durability of Ketos Steel is without equal.

When you have dies to make, you can't go wrong if you specify Ketos as the Steel to be used. It is Oil Hardening, Non-Shrinkable, and absolutely reliable. Let us prove its worth to you!

The Ketos Blue Book is interesting, valuable and free. Send for one.

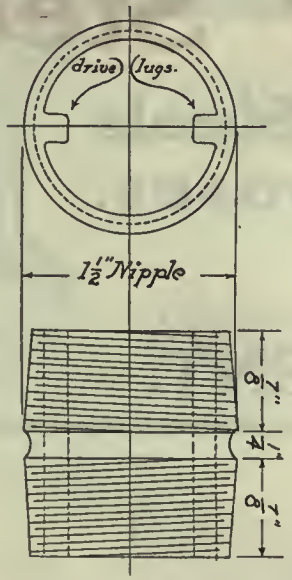
KETOS

SPEED!



Landis Machine Company, Inc.
Waynesboro, Pa.

The "Landis" Threads 2,000 of These Nipples Per Day

THERE is an interesting job in the line of threading nipples at the plant of the Fowler & Wolf Manufacturing Company, Norristown, Pa. The sketch shows what these nipples are and the photograph how they are threaded. One end receives a right hand and the other a left hand thread. Every one of these threaded nipples must have good, clean, full threads, because they are used on radiator work, and faulty threads would not be steam tight.

A double spindle Landis Bolt Threader is used, one side doing the right hand threading and the other side the left hand threading. Output is 2,000 nipples per day—4,000 threads.

The Landis bolt cutter has been in continuous service for the past six years, and not one cent has been spent for repairs.

Ask for the catalogue and more details of Landis Machines and Landis Die Heads.

Equip Efficient Tools with Efficient Drives

HIGHLY efficient tools are purchased to perform certain operations at a lower cost.

Effective as those machines may be, their maximum efficiency is largely dependent upon the form of drive used.

Link-Belt Silent Chain Drives deliver 98.2% of the power to the driven machine. There's no slippage of belts—no waiting for belt repairs—no inferiority of product due to ununiform application of power.

Every revolution of the motor shaft registers a like revolution of the driven shaft. Speeds are uniform. Greater speed reductions are possible. A better product results.

For Link-Belt Silent Chain Drives are "flexible as a belt—positive as a gear—more efficient than either". Write for our 40-page Machine Tool Drive Book No. 312. Shows many applications and gives full details.

CANADIAN-DETROIT TWIST DRILLS

CUT down the cost per hole by specifying them on your next order.

We make milled drills of all types and sizes.

We also manufacture the famous DD rolled drills, in all sizes from ½ inch to 1½ inches, specially designed for drilling drop forgings and hard alloy steel castings. The Double-D combines the strength of the forged drill with the accuracy and uniformity of the milled type. The rolling process, which we control exclusively, gives greater density to the steel, without introducing the rough inaccuracies of hammering. Try DD drills on the toughest operation in your plant and watch them "hog in."

We invite comparative tests.

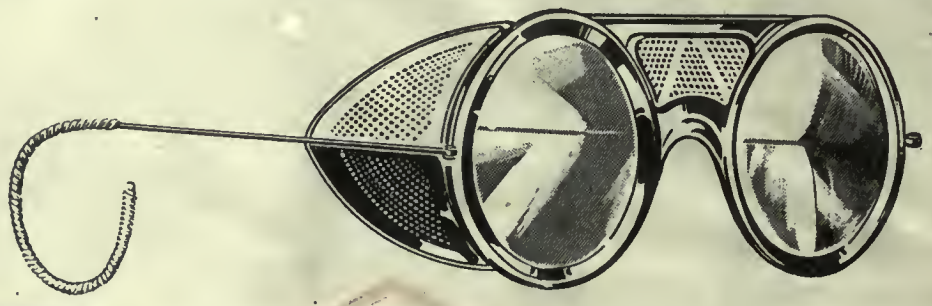
The Comfortable Way to Protect Eyes

STOCO SAFETY GOGGLES
(Pat. Dec. 12, 1916)

with

"CELOGLAS" Shatter-Proof Lenses



A safety goggle may be efficient in every other respect, but if it cannot be put on and then forgotten; if it cannot be worn day in and day out for long hours at a stretch without irritating the nose or tiring the eyes; if, in short, it is not thoroughly comfortable, it is not a practical protection glass—neither is it a STOCO Safety Goggle.

The patented one-piece front construction of the STOCO Safety Goggle, in addition to increasing the protection afforded (see illustrations) makes possible a very wide, smooth bridge, which comfortably distributes the weight of the goggle over a wide area instead of uncomfortably concentrating it on the sensitive bridge of the nose. This feature, combined with the light weight of the STOCO Safety Goggle, results in a protection glass that is truly comfortable.

Celoglas Shatter-Proof Lenses—laminated lenses which cannot shatter into the eye—are plane and practically colorless so that they cannot tire or strain the eyes. (Incidentally, STOCO Safety Goggles may be worn over regular glasses if desired.)

If you are responsible for the buying of eye protection for your shop or plant and have not yet found a really comfortable protection glass, we suggest that you try out the STOCO Safety Goggle. A request on your own or your firm's letterhead will bring you a sample by return mail. There will be no charge or obligation.

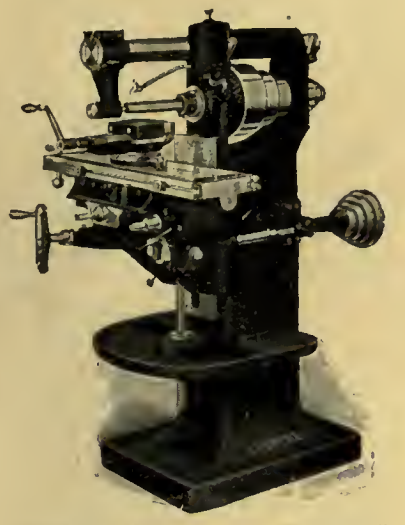
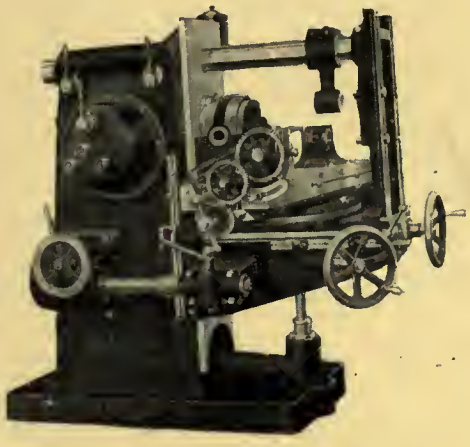
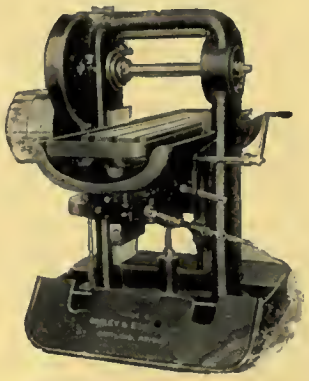
AND WOODWORKING MACHINERY



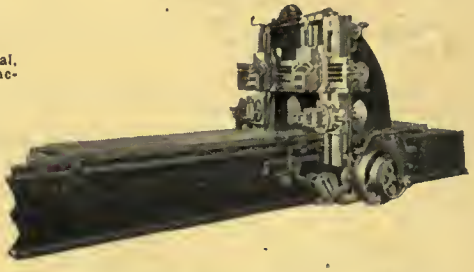
Small Milling Machines for your light work will save you money. Get our quotations.



Milling Machines, Plain, Universal and Vertical, of Cleveland, Ford-Smith, Milwaukee manufacture—sizes numbers one to four.

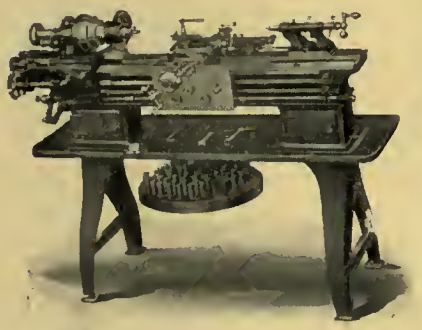


Briggs Millers, the greatest production millers ever developed. All sizes in stock.

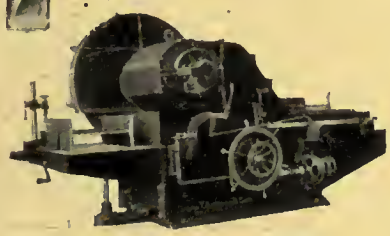


Planers, several used for immediate shipment. Standard and open side machines for good delivery.

The most powerful Air Drill made. All sizes in Toronto stock.



Cataract Quick Change Swing Precision Lathe, with Cone Drive. (Details in Special Catalogue).

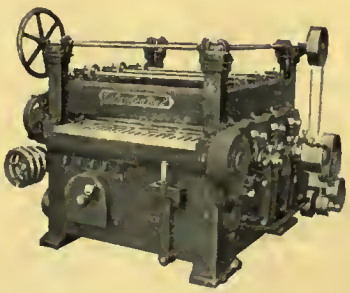


Ryerson Friction Saws for rapid cutting of steel shapes of all sizes. One No. 3, new, available at Toronto warehouse.

Hand Feed Jointer for your pattern shop. Sizes in stock 12" to 24".

Vertical attachments for your small millers will give you a perfect tool for die and small tool making.

The Lennox Rotary Bevel Shear; the most efficient machine made for beveling irregular and curved sheets. In Toronto stock, capacity 1" plate.



Surfacers, single or double. Can be had either with or without variable feed and sectional rolls and chip-breakers.

Universal Saw Bench for ripping, cross-cutting, dadoing, mitreing, etc. Indispensable for your wood shop.

32 FRONT ST. WEST, TORONTO TELEPHONE MAIN 5346

Interior View of Garlock-Walker Warehouse

20,000 Sq. Ft. of Floor Space Containing Every Variety of New and Used Machinery

YOU see merely a corner of our warehouse in the above illustration, but it will serve to give you an idea of the variety and extent of our line of machinery. Practically everything is found here for Woodworking and Metal-working purposes — lathes of all kinds, high speed drills, millers, planers, power hammers, electric and pneumatic tools — tools, in fact, of every description for shops large and small.

There are many used machine tools included in our exhibit, a number of them just as serviceable as new tools. It will pay you to look them over, for if they suit your purpose a considerable saving will result.

Remember this: Whether you are to personally inspect our stock or not you can place confidence in our desire and ability to furnish you with tools that will give absolutely good service. We aim to always supply our customers with machines best suited for their requirements. Success in this respect accounts for our continued and ever-growing patronage.

En-ar-co
SCIENTIFIC REFINING
"Crude oil is like a rainbow"
The elements of crude oil are so completely blended that it is as difficult to separate them as to separate the blended colors of the rainbow. To get complete separation through repeated distillations we make countless tests. Only in this way can the absolute purity of oil products be insured.

"The Oil of a Million Tests"

The secret of successful scientific oil refining is painstaking care and unceasing vigilance. In making EN-AR-CO oils we average over a million tests a year. It is only by this multiplying of tests that perfect products can be made. This thoroughness in our scientific refining processes is the protection we offer to users of our products.

We manufacture En-ar-co Oils and Greases to lubricate and operate every kind and make of machinery known.

EN-AR-CO OILS AND GREASES

have a reputation for perfect lubrication from the ordinary to the largest and most intricate machinery

En-ar-co Brands Stand for Quality.

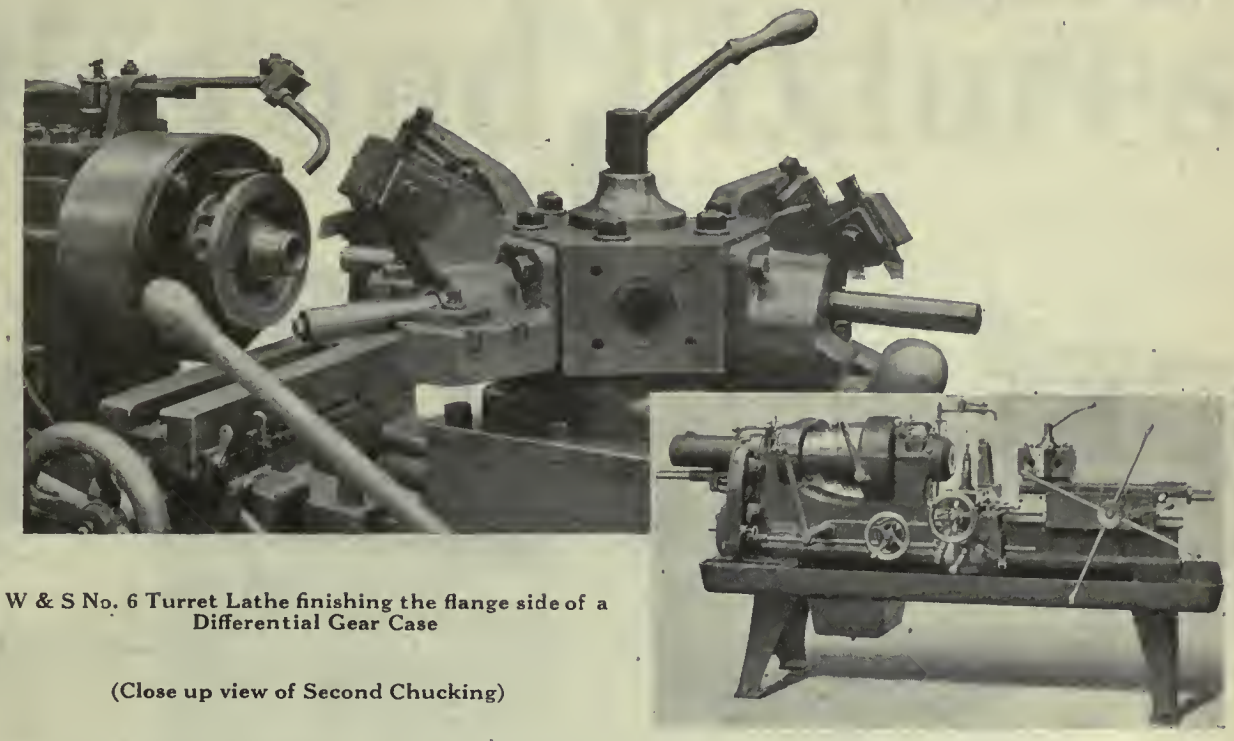
Everyone Considers Price



W & S No. 6 Turret Lathe finishing the flange side of a Differential Gear Case

(Close up view of Second Chucking)

Of course everyone considers price. And a thing is expensive or not in proportion to its value to you.

When a machine is built in such a way that it delivers service to you year after year without ceasing, it's worth something.

When a machine is built in such a way that its accuracy lasts year after year, you want to know about it.

When this accurate, durable machine produces your work faster and better than any other machine on the market, your costs go down and you know your investment in that machine is a paying one.

Warner & Swasey Turret Lathes are built just that way. We'd be glad for a chance to prove it to you—write us.

World's Largest Manufacturer of Turret Lathes and Turret Lathe Tools.

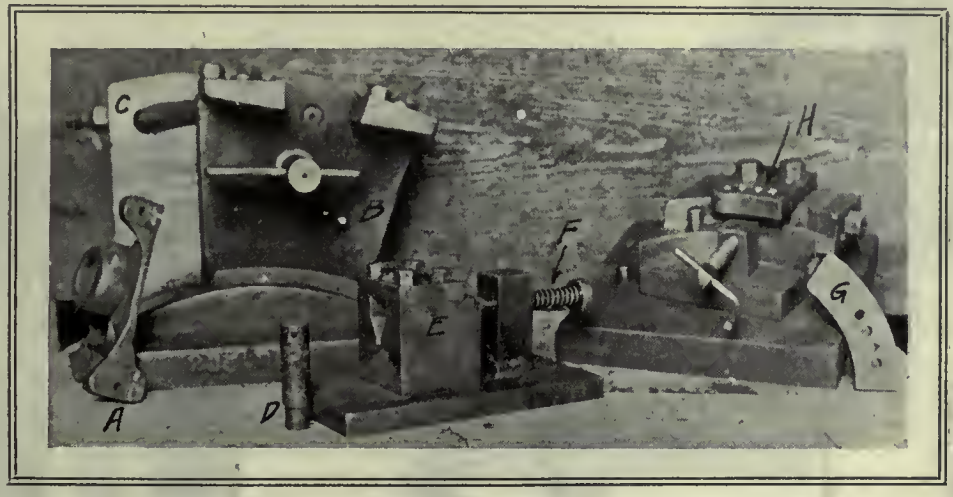
Jigs and Fixtures

For Real Service

YOUR particular attention is called to our **Jigs** and **Fixtures.** These are the result of years of specializing in this line. For real service you will find none better than those from the Elliott & Whitehall shops. Proof of these statements is evidenced by the many letters we receive from enthusiastic users. We will be glad to refer you to any of these.



Here is an example of the work of Jigs and Fixtures. They are used with much success by the plants turning out agricultural machines. We also cater to practically all the automobile plants in Canada on metal stamping dies, also jigs and fixtures, which are not only ideal for this type of work but are proven successes in many other lines.

Small Tools

And what is true of our Jigs and Fixtures is equally true of our **Milling Cutters and Small Tools.** Our list includes Plain and Side Milling Cutters, Inserted Tooth Cutters, End Mills, Interlocking Side Cutters, Angular, Concave and Convex Cutters, Gear Cutters, Hand Reamers, Checking Reamers and many others.

Send for our catalogue. It is replete with full specifications and details and tells all about this line of superior quality and service. Constant reference to it will increase shop efficiency.

If the Pyramids were built today—

PIECE by piece, with years and men no object, clumsy hand-power slowly built the ancient Pyramids.

But, today, when men and minutes count big, man-power stands little chance in a tug-o'-war with the swift lifting power of Little Giant Pneumatic Geared Hoists.

They lift from one to ten tons without a hitch, jerk or jolt. A Little Giant load never slips because its automatic air-brake always grips. It holds what it hoists. A protecting limit-stop prevents jam-ups from over-hoisting.

Hoist pneumatically! Reduced labor costs and increased production prevail wherever Little Giants are used. These rugged all-steel hoists put *lifting* on a *production* basis.

Capacities of from 1 to 10 tons, in stationary, trolley, and geared trolley types. Ask for instructive Pneumatic Tool Bulletins.

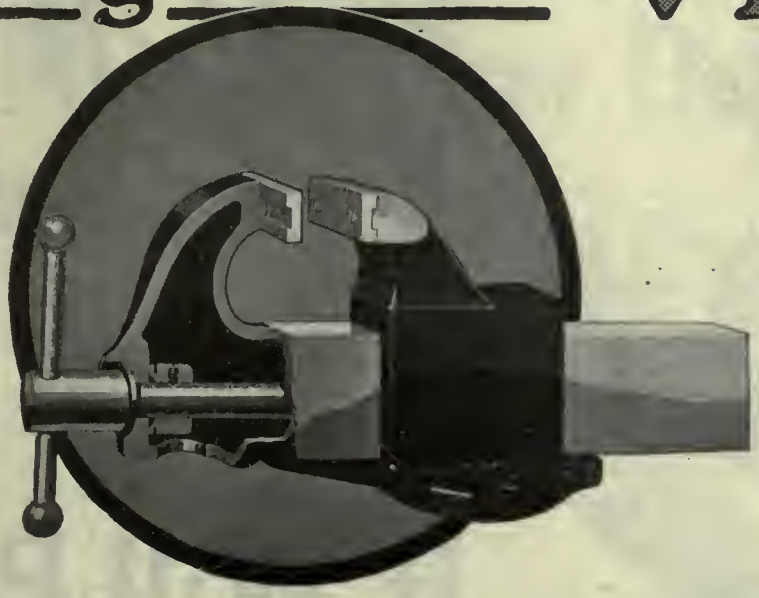
COLUMBIAN

Sledge-Tested VISES



The Hollow Jaw IS Stronger

EVERY mechanic knows that a hollow tube has greater bending strength than a solid bar of the same weight of material. By actual test a tube 5 feet long is about three times as strong as a solid bar of the same weight and length.

Columbian Sledge-Tested Malleable Iron Vises are built according to this widely used principle of mechanics. The hollow jaw construction makes them much stronger than solid vises of the same weight. This construction, as applied to vises, is patented and can be used by no other manufacturer.

Columbian Sledge-Tested Vises are the only vises made of malleable iron. This feature alone makes them twice as strong as cast iron vises. The jaws will not chip, crack or break.

Removable steel jaw faces, cold-rolled steel handle with forged ball ends that never come off, are additional advantages that make Columbian Sledge-Tested Vises standard equipment in many of the largest machine shops in the world. They are a distinct aid to large-scale production.

The City of *St. Johns* Quebec

It Will Pay You to Bring Your Plant to

the City of

St. Johns

QUEBEC

Everything Here a Progressive Manufacturer Desires

The City of St. Johns Offers Real Inducements

EXEMPTION of taxes for fifteen years' period, subject to extension; all public improvements required, such as street extensions, sidewalks, waterworks and sewage; five per cent. bonus on your payroll for five years! Such are the inducements offered to you to bring your plant to St. Johns, a city with a promising future in the province of Quebec.

LOCATION St. Johns is on the Richelieu River (27 miles from Montreal), provides the city with a direct water route to the Eastern Seaboard of the United States and the Great Lakes. Its commanding position in relation to the important markets of Canada and the United States assures economy and dispatch in the assembling of raw materials and distribution of the finished product.

POWER A plentiful supply of power is developed at Chambly, eleven miles north-east of the city and distributed in St. Johns at rates that will compete with any city or town in Canada. Excellent railway connections assure a satisfactory coal supply.

SHIPPING Seven railroads, including Canada's two great transcontinental lines, run through the city. St. Johns obtains lower freight rates than any other centrally-located point on the continent.

LABOR St. Johns is known as the cheapest labour market in Canada. Skilled and unskilled labour is always plentiful and labour troubles are unknown.

In addition to the natural advantages of St. Johns as a location for a new industry, the city greatly reduces the initial expense and difficulties of organization by granting many extraordinary inducements and concessions.

Facts About St. Johns You Should Keep Before You

—Seven railroads, including Canada's great transcontinental lines.
—Finest ocean shipping facilities.
—Canal connections with New York, the Eastern States and the Great Lakes.
—Cheapest labor market in Canada.
—Plentiful supply of skilled and unskilled labor.
—Cheap and abundant electric power.
—Cheap coal and lower freight rates.
—Desirable factory sites with tax privileges.

WILLIAMS' SUPERIOR DROP-FORGED CLAMPS

THERE'S a Williams' Clamp for every purpose.

If it's extreme strength and heavy service—Williams' "Vulcan" line provides both. 11 sizes, ¾ to 12½ inches capacities.

If it's general utility—without need for maximum strength—Williams' "Light Service" line will fit the case, 8 sizes, 2 to 12 inches capacities.

If it's stability and utility—medium service—Williams' "Agrippa" line offers the solution. 7 sizes, 4 to 18 inches capacities.

If it's Tool Room work requiring comparatively small openings of jaws — Williams' "Vulcan" Tool Makers' line should be chosen. 4 sizes, 1 to 4 inches capacities.

All are made of a special, high-grade steel. After forging they are subjected to a refining process, or heat treatment, which increases their stiffness and strength and reduces the liability of springing.

MACHINISTS' TOOLS BOOK ON REQUEST

J. H. Williams & Co., Ltd.

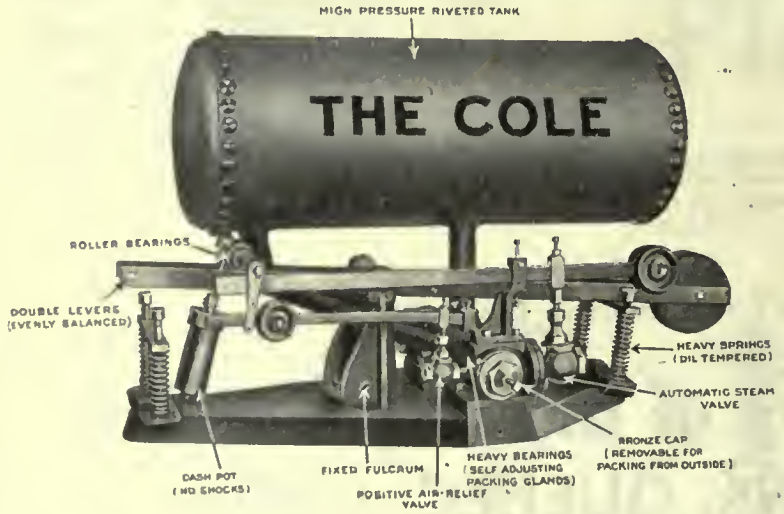
"The Drop-Forging People"

Formerly Canadian Division of The Whitman & Barnes Mfg. Co.

45 Thorold Road, ST. CATHARINES, ONTARIO

The "COLE" For COAL ECONOMY

The "COLE" Trap has self-adjusting packing glands, operating on Roller bearings, on a fixed fulcrum which permits of full discharge at each operation.



The Return Trap will receive water from Lifting or Non-Return Trap, or High or Low pressure and return back and into boiler.

The Lifting Trap will receive water from any pressure and discharge to Return Trap.

The Non-Return Trap will hold back the steam and discharge the water into any receptacle with lower pressure than coil to be drained. It has a valve opening as large as the pipe connection and will cause no more friction than 20 ft. of pipe.

Full information on request.

Locate Your Factory Here!

Eight Good Reasons!

1. It has the best of lake shipping facilities.
2. Its railway connections are unexcelled anywhere.
3. It is close to the big manufacturing States of the Middle West, Michigan, Ohio, Illinois, etc.
4. Its location makes it a central distributing point for the trade of the entire Dominion.
5. Abundant electric power is available at reasonable rates.
6. Plenty of skilled and unskilled labor are obtainable.
7. It offers the best of manufacturing sites with both rail and water shipping facilities.
8. Liberal concessions in tax exemptions, street extensions, etc., can be obtained.

THESE FACTS ARE WORTHY OF THE SERIOUS CONSIDERATION OF EVERY MANUFACTURER. WRITE NOW, FOR MORE DETAILED INFORMATION, TO

"Stubby"

A New Type Bridge Reamer

"Stubby" is about 25 per cent. shorter than the regular length bridge reamer, and the taper of the flutes is considerably sharper.

This results in a stronger, cheaper reamer which will materially lower reaming costs.

A "Stubby" reamer in the chuck of an air or electric drill is more easily handled—awkwardness of finding the hole and getting to work is done away with. "Stubby" Reamers will ream out a hole in little more than half the time required by the old-type bridge reamer.

All "Imco" Tools are good tools — built to remove more metal in less time; to be more accurate; to last longer between grindings; to have longer life!

Catalog of "Imco" 3 and 4-lip drills, reamers and milling cutters upon request.

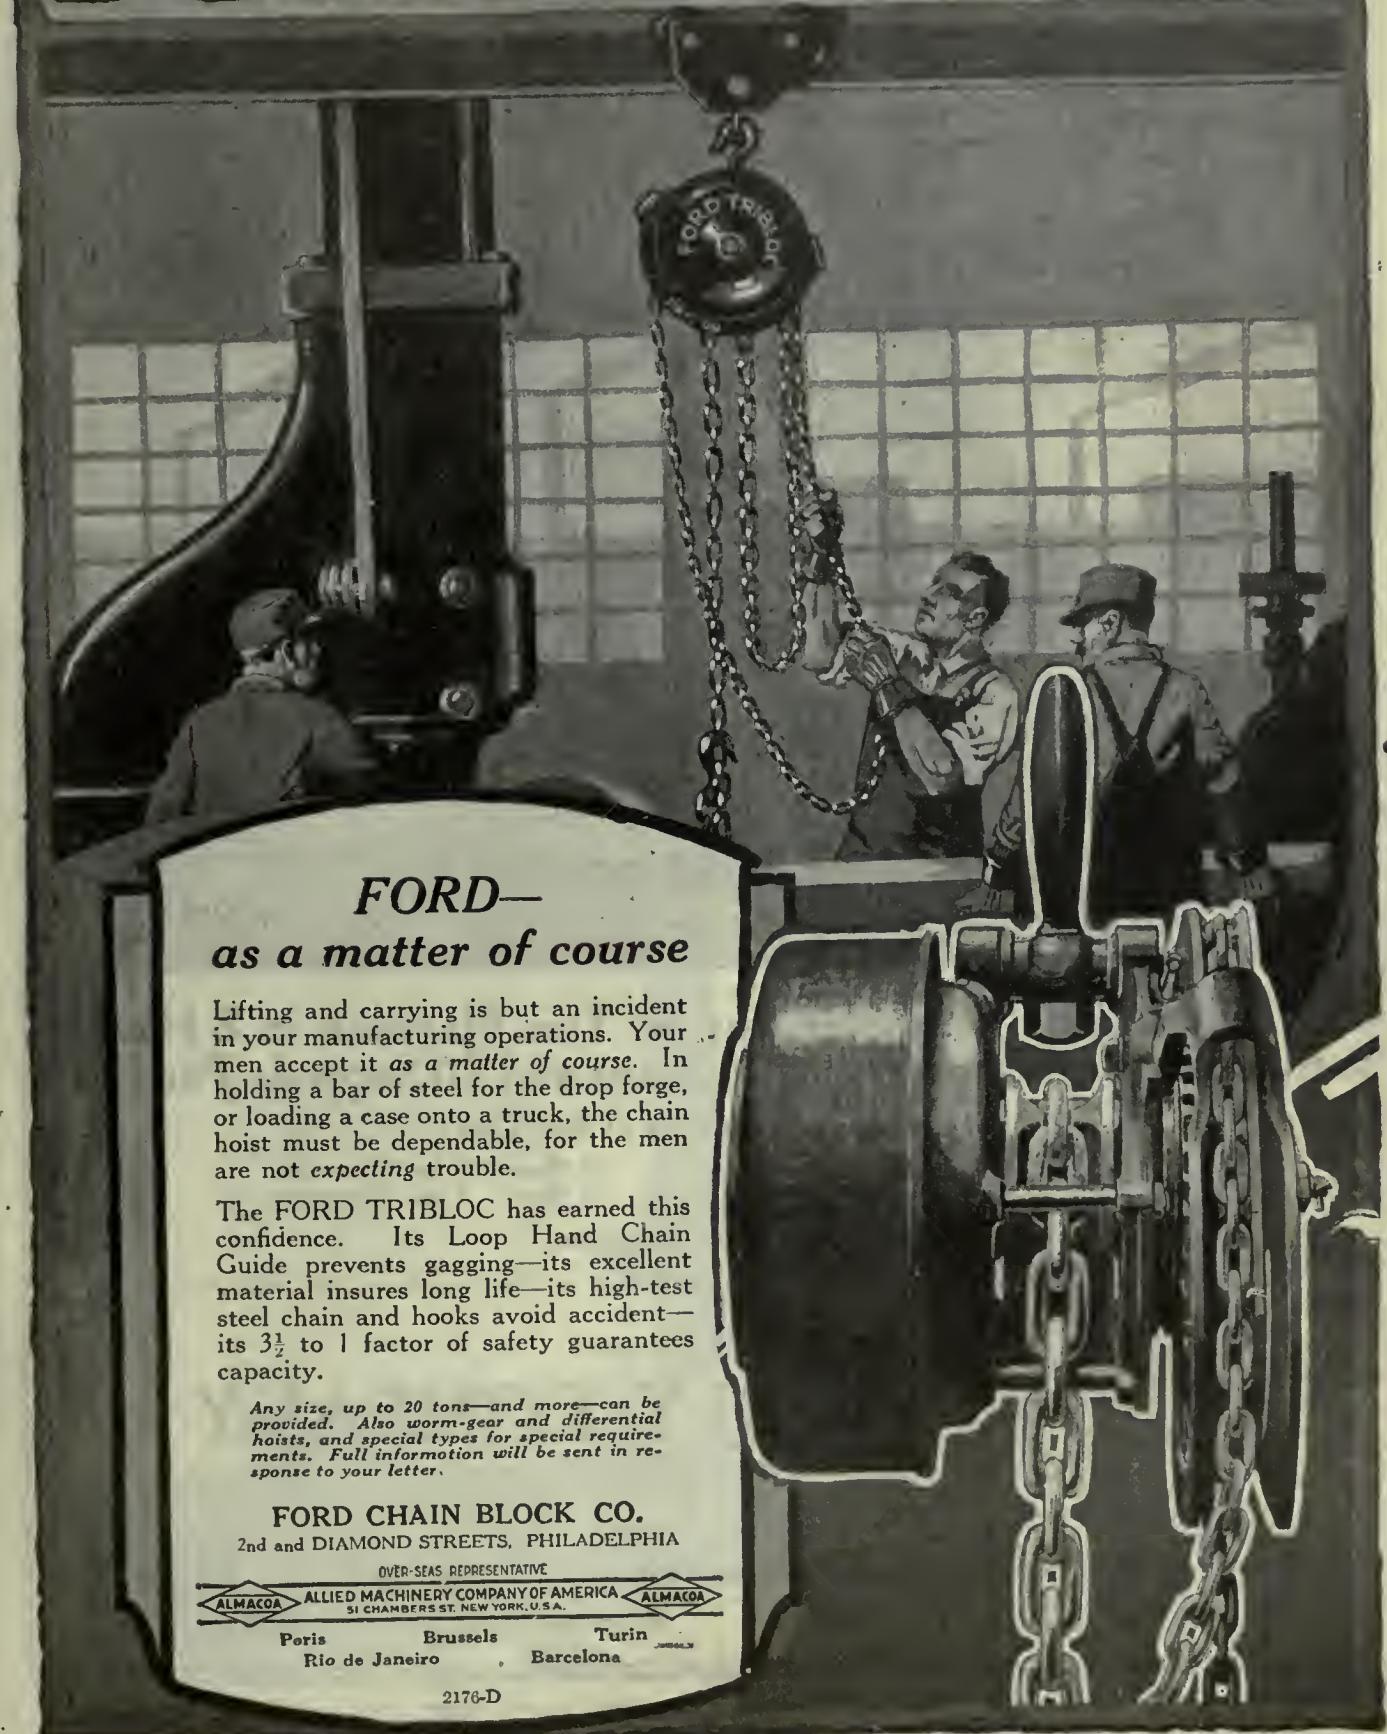
FORD TRIBLOC



FORD—
as a matter of course

Lifting and carrying is but an incident in your manufacturing operations. Your men accept it *as a matter of course*. In holding a bar of steel for the drop forge, or loading a case onto a truck, the chain hoist must be dependable, for the men are not *expecting* trouble.

The FORD TRIBLOC has earned this confidence. Its Loop Hand Chain Guide prevents gagging—its excellent material insures long life—its high-test steel chain and hooks avoid accident—its $3\frac{1}{2}$ to 1 factor of safety guarantees capacity.

Any size, up to 20 tons—and more—can be provided. Also worm-gear and differential hoists, and special types for special requirements. Full information will be sent in response to your letter.

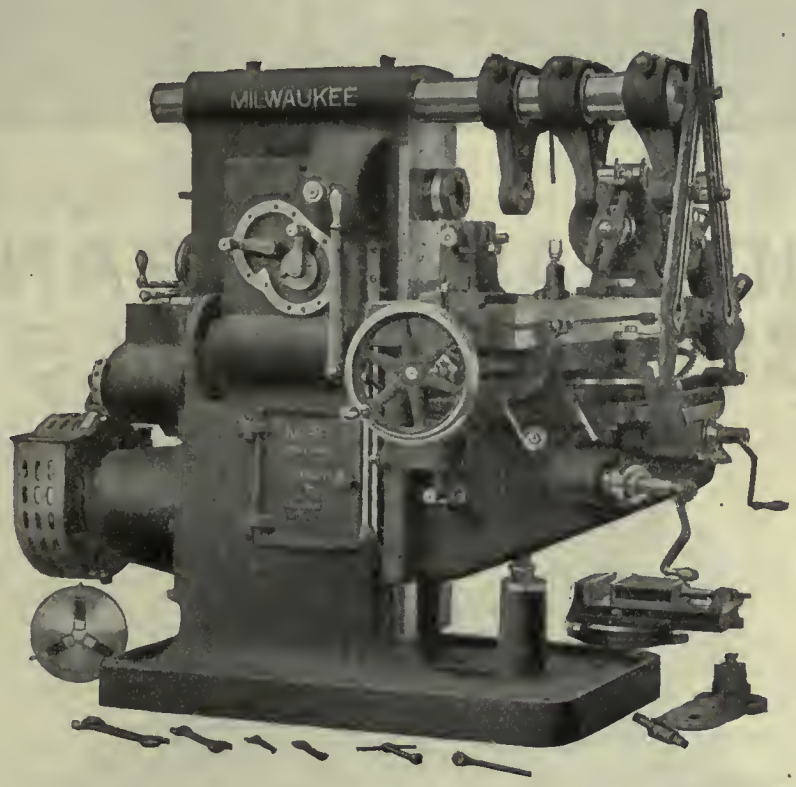
Milwaukee Universal Milling Machines



Superior Service in the Tool-Room

Milwaukee Universal Milling Machines are accurate, rigid and flexible, and are distinguished for their efficiency on all kinds of milling done in the tool-room. Light or heavy operations are as one to the "Milwaukee."

A really scientific construction with all parts of the machine properly proportioned so as to form practically a single unit; features to reduce supervision, maximize ease of operation and increase the accuracy, rigidity and entire efficiency of the machines, make Milwaukee Universal Milling Machines the choice for the tool-room.

Firms that seek the certainty of tool-room satisfaction under all conditions find their hopes realized in the "Milwaukee."

Our catalogue No. 22 will be gladly sent to you on request.

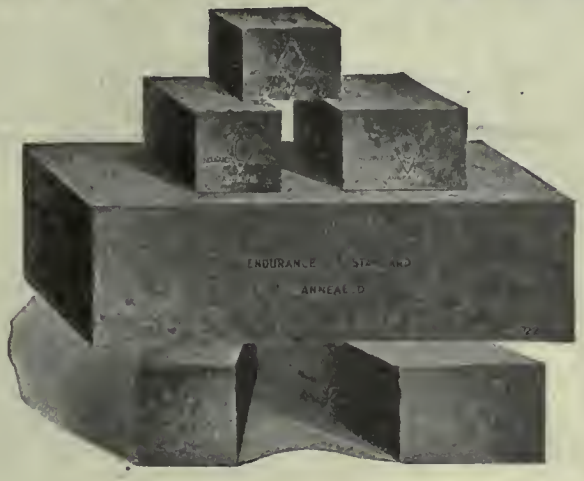
NI-KROM DIE BLOCKS



GRADE—This is our first grade block hard and tough and recommended for long runs of forgings.

DESCRIPTION—NI-KROM Die Blocks are forged from an alloy steel having both Nickel and Chrome content.

IDENTITY—On two sides of these blocks will be found this symbol:

NI-KROM  Annealed

WARRANTY—These NI-KROM Blocks are warranted against flaws, pipes, seams and forging defects. Where impressions must maintain exact dimensions, and long runs are desired, this block is recommended for both duration and economy. This block must be hardened before using in a hammer.

HEAT TREATMENT

If so ordered WE will give this NI-KROM Block expert heat treatment which will increase the hardness quality by about One Hundred per cent. over the annealed block. This quality of hardness will be equal throughout the entire block and will make it more difficult for the Die Sinker to work, but as soon as the impression is sunk the Blocks are ready for immediate use in the hammers without any other treatment. Impressions may be renewed and immediately used again without annealing or further heat treatment.

IDENTITY—When these Blocks are heat treated in our plant before shipment, on two sides will be found this symbol:

NI-KROM  Treated

Extra Charge is made for this service.

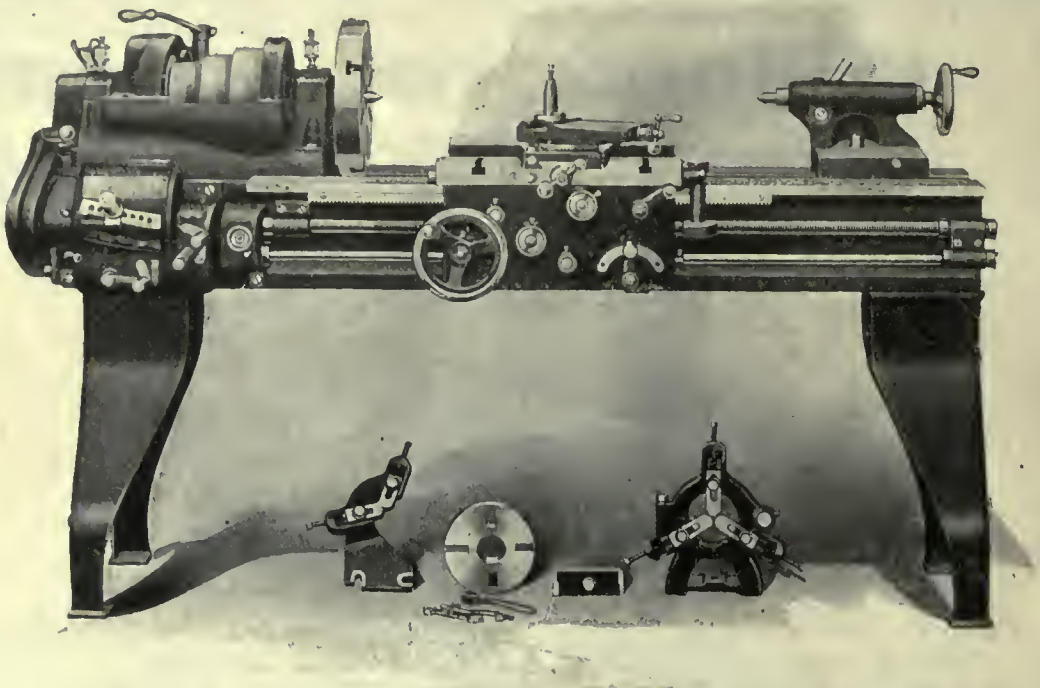
NOTHING BUT FORGINGS

The "ECONOMY"



"ECONOMY" 14-inch Swing, Double Back Geared Quick Change Engine Lathe

THE "ECONOMY" 14-inch Engine Lathe is especially designed to meet the demands for a small, heavy-duty machine of sufficient weight and power to handle the rapid production of the modern manufacturing plant. Being high grade and extremely accurate, it is a suitable machine for the tool room, and also general repair and garage work.

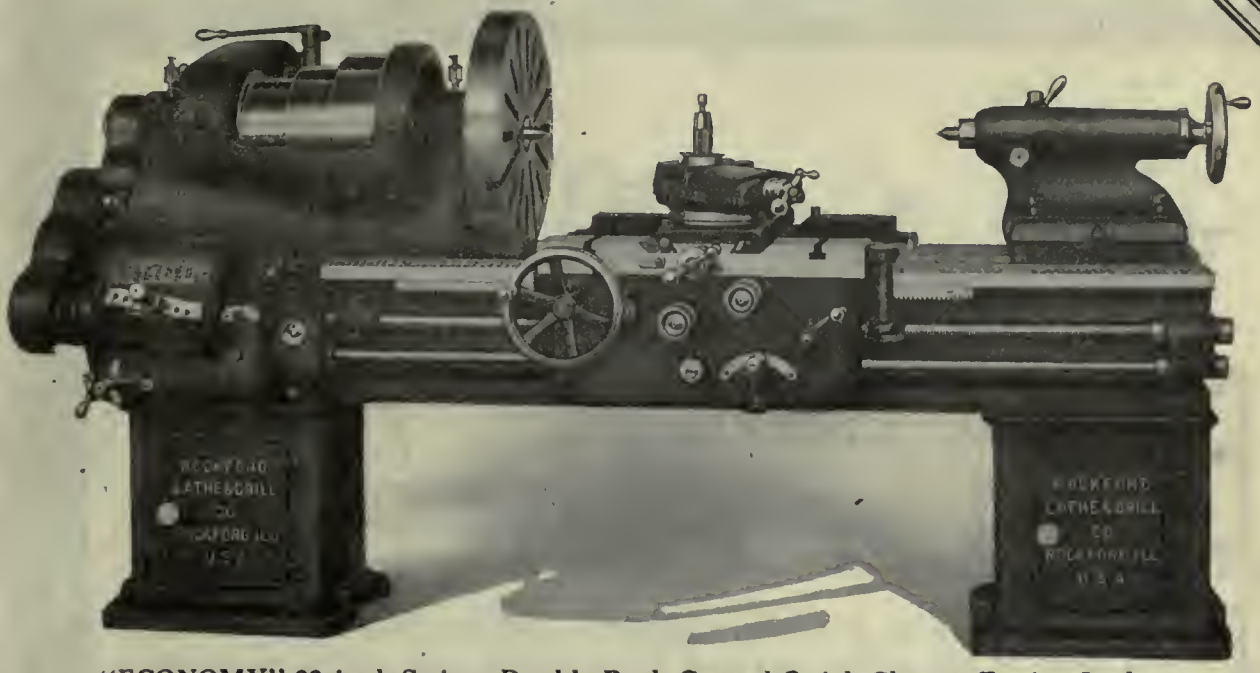
The headstock is massive and firmly bolted to the bed and has a three-step cone of large diameter for a 2½" belt. The double back gears are conveniently shifted from the front and are provided with a safety device which makes it impossible to lock the gears or strip the teeth. The bearings are exceptionally large, of a special composition metal, and are carefully machined and hand-scraped to fit spindle. The spindle is of high carbon steel, accurately ground, and has a 1 5-16" hole its entire length, and is provided with special thrust bearing of alternate collars of hardened steel and bronze. The double friction, self-oiling countershaft has pulleys 10" diameter with 3½" face.

"Economy" Lathes are also built in 12", 18" and 22" swing sizes. Our catalog explains the four sizes and also the various attachments in detail. Shall we send you a copy?

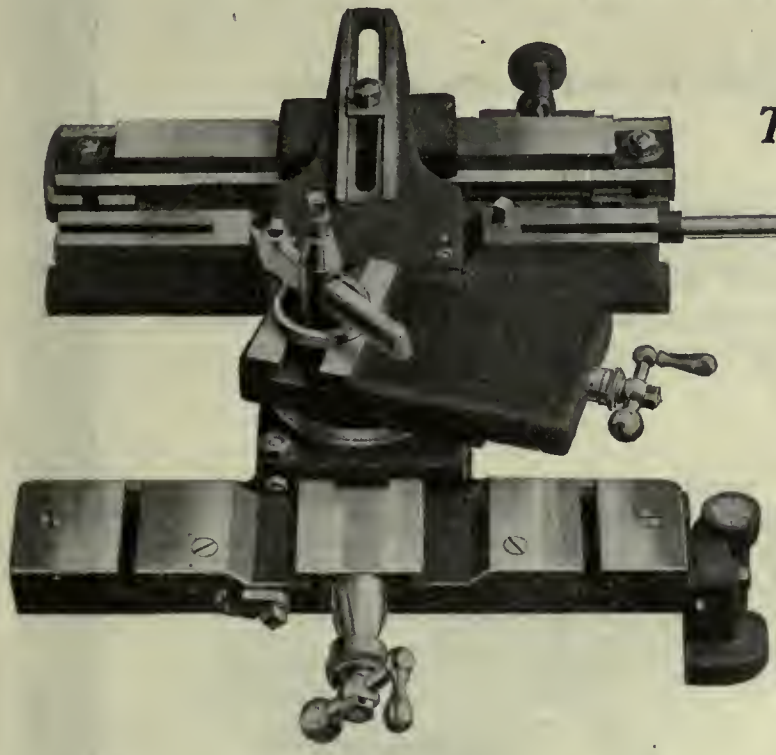
Rockford Lathe

Builders of Engine Lathes

Rockford,



"ECONOMY" 22-inch Swing, Double Back Geared Quick Change Engine Lathe



Taper Attachment

ON the left is illustrated the taper attachment as furnished for our 12", 14" and 18" lathes. Its design is simple and consists of very few parts and its construction is extremely sturdy. No special bed is required; as all carriages are drilled, this attachment may be applied at any time. It is permanently fastened to the back of the carriage, making it instantly available at any position on the bed.

The regular compound rest and cross slide are used. The extra extension required is furnished with attachment and is interchangeable with short one supplied with regular lathe equipment.

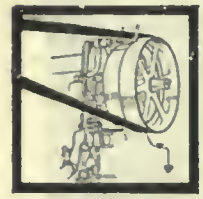
BELTING

For Transmission

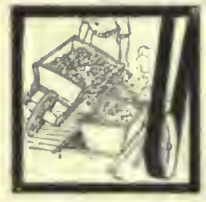
SCANDINAVIA BELTING — TORONTO

For Conveying

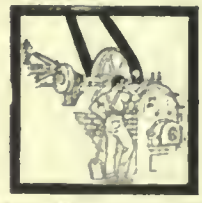


GOOD ON BELT SHIFTERS

GOOD IN OILY PLACES



GOOD IN DUSTY PLACES



GOOD IN HOT PLACES

For Conveying

Use the regular Scandinavia Belt for conveying abrasive materials such as coal, rock, ore, coke, etc., and you will be surprised at the material it can handle per dollar cost.

For non-abrasive material use our special conveyor. This is especially adapted for handling clay, pulp, sawdust, sand, etc.

And the price is very reasonable.

For Transmission

The illustrations to the left indicate where this belt can be used to advantage. This belt makes a good general service belt except for driving in cold temperatures.

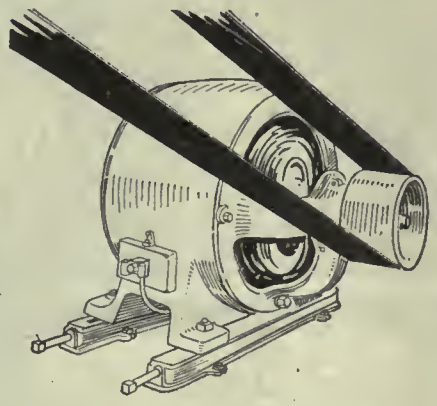
BELTING

Lanco Balata Belts For Transmission

They Last Longer

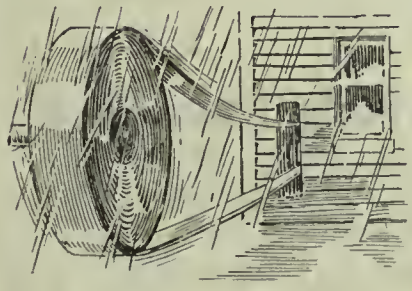


It's all in the Quality

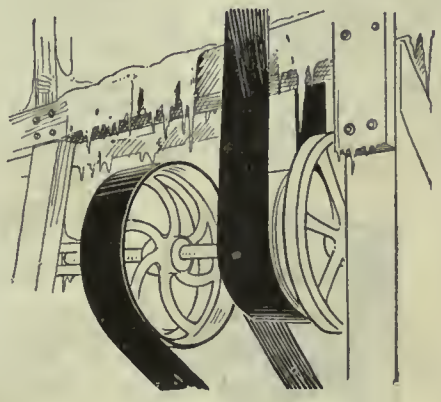
The high quality of **Lanco Balata** is a well-established fact. This belting is strong, pliable, really waterproof, and is in good condition long after an ordinary belt is worn out.

From the standpoint of economy

You will find that no other belting will give the same long service in so many ways as **Lanco Balata.**



TRADE MARK
LANCO BALATA
BELTING



FEDERAL ENGINEERING CO., LIMITED

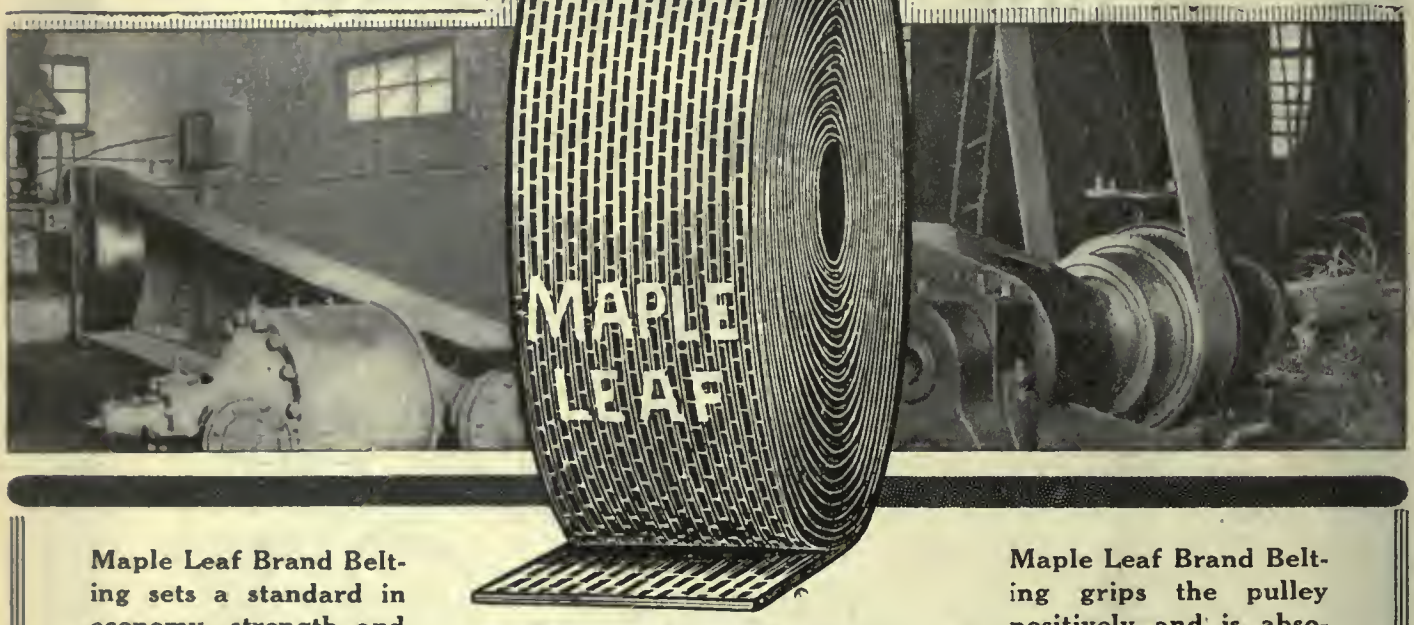
MAPLE LEAF BRAND

STITCHED COTTON DUCK



Maple Leaf Brand Belting sets a standard in economy, strength and durability.

Maple Leaf Brand Belting grips the pulley positively and is absolutely true running.

BELTING

For transmission of power or conveying purposes Maple Leaf Brand Belting is as efficient as any belting you can buy. It costs less than leather, rubber or balata. Figured on a basis of "service per dollar" it is the best belting buy on the market. Satisfied users throughout Canada will verify these statements.

A recent test at a Canadian university proved that Maple Leaf Brand Belting will stand a breaking strain 50% greater than leather and 25% greater than rubber.

We will gladly send samples and price list on request.

Maple Leaf Belt Dressing

BEST FOR ALL KINDS OF BELTS

Maple Leaf Belt Dressing does not contain resin, mineral or animal oils or other ingredients harmful to belts.

All belts should have an occasional application of a reliable dressing in order that the best results be obtained. We recommend Maple Leaf Belt Dressing as the safe and sane treatment.

Power is Expensive—SAVE IT

But not by reducing production.

In fact, by the use of ball bearings, you can largely increase production and consume no more power than formerly, for in the average plant friction destroys at least 25 per cent. of all the power produced or bought.

High grade ball bearings, such as S K F and Hess-Bright, are almost frictionless. Not only is less power required, but belting life is lengthened, wear is practically eliminated, bearing renewals are postponed almost indefinitely, frequent tying up of equipment is avoided, oil costs are lower, and hot boxes are unknown.

Ball bearings, by conserving the energy formerly wasted, benefit the whole power line from the machines back to the boilers.

Transmission Hangers

A Service that contemplates more than the sale of a bearing.

Every S K F Industries service-salesman is a plant engineer equipped to consult on your bearing problems. S K F Service made available through these men is built on a laboratory-backed ideal that seeks to increase Canadian output by lifting the friction load from industrial machinery.

Manufacturers are invited to avail themselves of this freely offered co-operation.

The SKF Research Laboratories where friction problems are solved

An installation of automatic screw machines in a large machine shop—Equipped with G & K belts

This trademark is the symbol of the scientific control of tanning and manufacturing processes and the application of the correct belt for every drive in every industry.

"Aw, you can't scare me"

"BRING on your deep cuts, your oil and cutting fluids, shift me frequently, you can't scare me or stop me," says the sturdy G & K belt.

"I'll pull your machine right through peak loads without a bit of chatter or slowing up, whether it's an automatic screw machine, a grinder, planer, miller or what not. No difference to me! Just watch me turn out the work!

"You fellows who have had belts that slipped and slowed down the machine so that you had to back up and start over, or take a shallower bite—you are the boys who can appreciate me.

"I do the work right because I was built especially for the job by G & K engineers who knew what I'd run into after they had said good-bye to me.

"Those engineers have prepared a book, 101F, that specifies the correct belt for every drive in the machine shop and gives a lot of handy 'dope' on belting. Better write 'em for it—they'll be glad to send a copy free."

Buy Belting to Fit the *Work*

THE sure way to buy belts is by giving a belting expert *all* the particulars of the drive.

The size of pulleys, speed and load are not the only factors in belt application.

Goodyear manufactures different types of belts for different uses. And Goodyear trains men to apply these belts to particular drives.

Goodyear Blue Streak is particularly adapted for abnormal conditions—big drives—heavy loads—short centres—intermittent loads.

Goodyear Klingtite fits general needs—the medium drives. Fully 80 per cent of drives can be successfully belted with Klingtite.

Goodyear Glide is probably the belt we will recommend for exceptionally fast drives on small pulleys.

But there is a tremendous number of combinations of speed, load, size of pulleys, atmospheric conditions, which affect not only the type of belt, but also the size.

Certain qualities, however, these belts have in common. All are of special Goodyear construction, which resists ply separation and opening at the seam; makes belts flexible and pulley-hugging without sacrificing strength. All have the Goodyear friction surface which offsets slipping. All have a world-wide reputation for trouble-free, economical service.

When you order a belt you need not order by name or size. Send the particulars of the drive to our belting department or give them to a Goodyear belting man. Our recommendation can then be scientific. You do not obligate yourself in any way by getting our recommendation. Just phone, wire, or write the nearest branch.

The Goodyear Tire & Rubber Co. of Canada, Limited

Branches: Halifax, St. John, Quebec, Montreal, Ottawa, Toronto, Hamilton, London, Winnipeg, Saskatoon, Regina, Calgary, Edmonton, Vancouver Service stocks in smaller cities.

In giving us details of your drives, tell us pulley sizes, distance from centre to centre, speed of drive, load transmitted; also tell us of atmospheric conditions—hot or cold, wet or dry, dust or other unusual factors. Tell us what belt you have been using and what service you have been getting. If belt has been slipping, have you been using dressing. If it breaks at fasteners what type of fastener are you using. Are there any idlers or shifters on the drive. Are pulleys properly aligned. Give us every detail so that your belt will be practically made to order.

GOODYEAR BELTS

MADE IN CANADA

KLINGTITE GLIDE BLUE-STREAK

FACTORY, FOUNDRY MILL AND MINE

All have their transmission problems to overcome. In many cases the belting used is of an inferior grade, or is not suited to the working conditions. This results in loss of power and general waste. To plant superintendents and engineers we recommend "P.M.S." Belting for use wherever conditions of heat, dampness or mechanical awkwardness makes transmission difficult. Consult our experts: they are at your service.

"WAUSITE"
Abrasive Cloth

Indispensable in every metal working shop

"Chief Ruff Stuff"

"Wausite" is a product of the electric furnace. It is recommended as the hardest and sharpest abrasive ever produced. Adapted to finishing all metals, including the hardest alloy steels.

"Wausite" Cloth. Far superior to emery. In 9 x 11 sheets, put up in quires (24 sheets) and ¼-ream packages (120 sheets).

Wausite "Waterproof" Strips in 10-yd. coils. A new and convenient way of putting up abrasives. No waste from tearing. Has uniform width and clean cut edges. Furnished in ½, 1, 1½, 2 and 2½-inch widths. All grits.

Also supplied in 50-yd. rolls of any width and grit.

Wausite Discs. In all standard diameters and grits; and in three thicknesses—Regular, Heavy and Extra Heavy—covering all requirements of disc-grinding practice. The Extra Heavy (HH) grade has no parallel in the industry.

Wausite Discs are made in two formulas—"A" for hard metals and "C" for soft metals.

Immediate Shipment from Stock

Send for working samples, prices and "grit cards." Free.

Canadian Distributors Wanted

We invite correspondence with well-established distributors with sales organizations, competent to develop Canadian markets for our products, which include not only the above-named lines, but the full range of garnet and flint cloths and papers for use in woodworking; emery cloth and paper and other abrasive products.

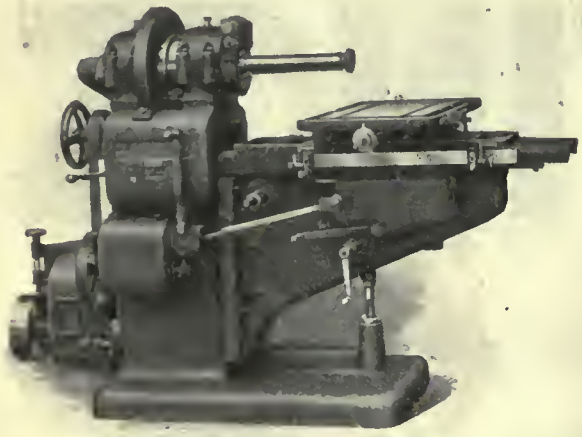
HEALD



STYLE No. 60 CYLINDER GRINDER

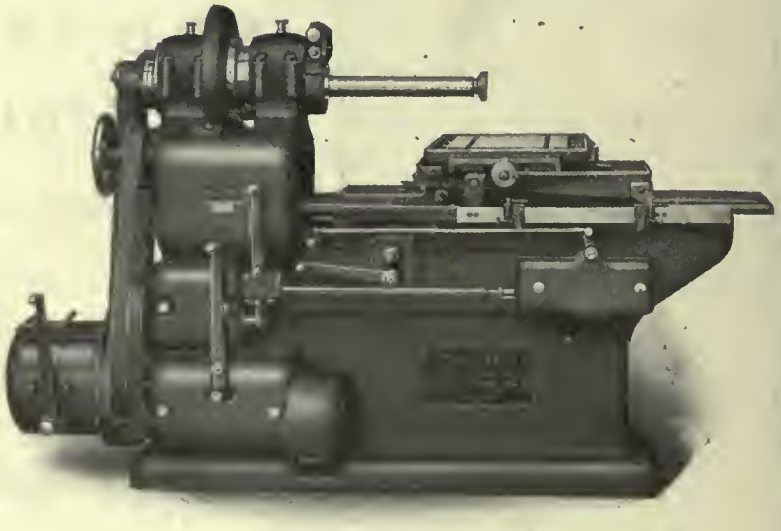
The Heald Cylinder Grinders are especially designed for internal grinding of holes in work of such shape that it is inconvenient or impossible to rotate in the usual manner when machining.

These machines are especially valuable for grinding airplane, marine or automobile engine cylinders. The ordinary method of smooth boring and reaming results in inaccuracies due to hard and soft spots in the casting, as well as springing of the thin cylinder wall. In grinding, the wheel revolves at a high speed in a true circular path, getting hard and soft spots alike, leaving an absolutely round hole.

Railroad shops are now using them to grind bearings in valve motion parts and piston rods, valve rods or brake parts, such as triple valves, etc.

Machine Style No. 60, as shown above, has a large vertical adjustment of 3½ inches, obtained by movement of the knee casting clamped to the bed. This machine is particularly suited to garage work or any shop where a variety of different sized work requires a large vertical adjustment.

Machine No. 65 is our latest style, built for precision and production work. Notice the massiveness, giving rigidity,—centralized control of levers, giving convenience of operation, and that it is self-contained.



STYLE No. 65 CYLINDER GRINDER

THE HEALD MACHINE CO.

BRANCH OFFICES—New York, 839 Singer Bldg., Philadelphia, 1808 Commonwealth Bldg.; Chicago, 26 South Jefferson St.; Detroit, 401 Marquette Bldg.; Cincinnati, 311 Provident Bank Bldg.; Cleveland, 721 Engineers Bldg.; WESTERN AGENTS—Eccles & Smith Co., Los Angeles, San Francisco, Portland, and Seattle; Salt Lake Hardware Co., Utaha, and Idaho; Hendrie & Bolthoff Mfg. & Supply Co., Colorado, and Wyoming.

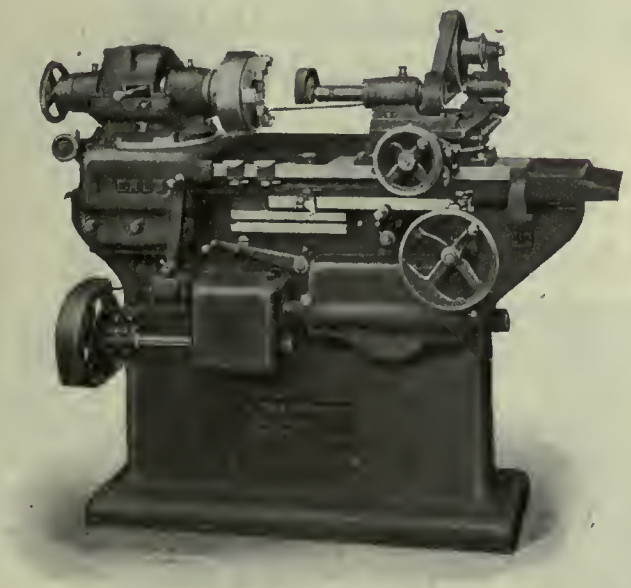
INTERNAL GRINDERS

Heald Internal Grinders are built to handle work which can be easily revolved, such as bushings, cutters, ball races, hardened gears, gauges, cones, etc.

Each wheelhead is made up in a separate unit, instantly interchangeable. Twelve sizes of heads enable these machines to cover a wide range of work, which, together with the swivelling of the workhead, makes this machine indispensable in tool-rooms for grinding straight and tapered holes.

STYLE No. 85 INTERNAL GRINDER.

Style No. 85, as shown above, and whose capacity is 10″ swing by 2″ long, was built for small, short work. The construction is very simple, and a large number of mechanical features have made it exceptionally well suited for rapid production. It works best on holes smaller than ¾ dia. x 1½ long.



STYLE No. 70 INTERNAL GRINDER

Style No. 70 handles work 15″ dia. x 11″ long. It has both automatic and hand feed for the table. Several new features have been lately added, including friction clutch workhead for starting and stopping the work, longer base to enable the operator to run the wheelhead back when plugging. Also the guard over the wheel has been re-designed so that it entirely covers the wheel.

Let us send you catalogues, together with literature showing these machines working in various factories.

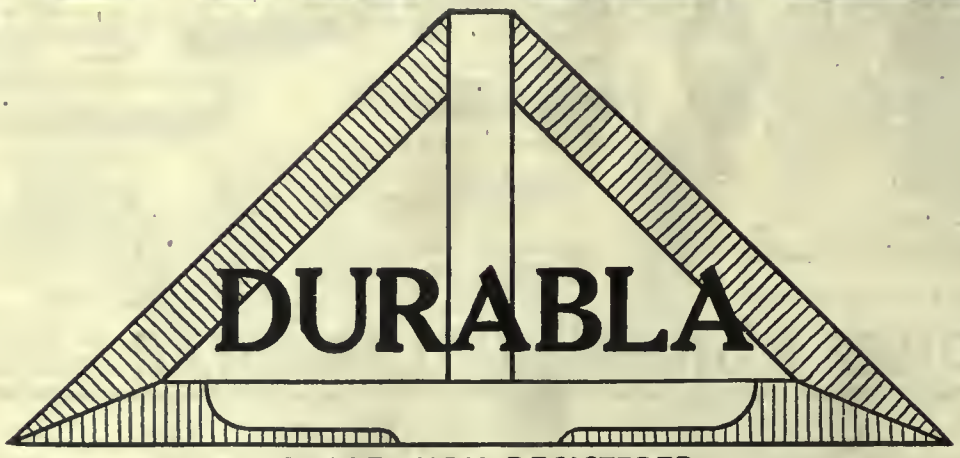
DURABLA



TRADE MARK REGISTERED

STRENGTH—GOODNESS—QUALITY

Performance Facts of Durabla Gasket Material

Tight joints are made and maintained by DURABLA under the following severe services and conditions:

Steam:	275-300 lbs. pressure; 275°-300° superheat.
Oil:	Pressure still joint re-made over 160 times.
Gasoline:	Cylinder heads of gasoline engines and pumps.
Acids:	All acids that can be carried in pipe lines.
Water:	Equally satisfactory with temperature of 40° or 210° F., at any pressure.
Ammonia:	Both absorption and compression systems of refrigeration.
Air:	Air lines and cylinder heads of compressors—all type.

One standard material for all gasket work—Sold on a Service Basis

DURABLA is sold in sheet or gasket form and the trade mark is stamped all over the material.

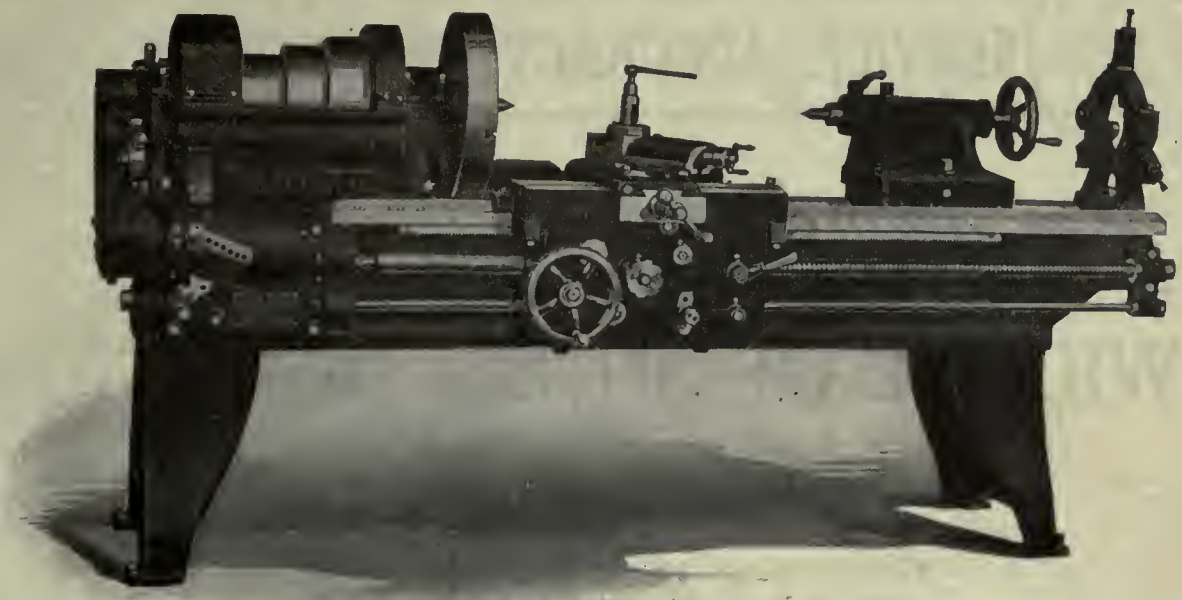
THE SIDNEY MACHINE TOOL COMPANY



SIDNEY

HIGH DUTY 17 INCH LATHE

SIDNEY for SERVICE

A producer of the first quality in accurate, heavy duty manufacturing—ready at all times to meet the most exacting demands of modern shop practice.

All the modern improvements in late design evolved by the strenuous demands of hard service have been embodied in Sidney Lathes.

Some features of this machine which have adapted it to heavy duty work: Closed type headstock offset from centres. 50 point carbon steel spindle, phosphor bronze spindle bearings and sight feed oil cup on front box. All other bearings fitted with Brown & Sharpe oil plug. Tail stock of improved rigid split type. Bed very heavy and deep, cross braced with double wall cross girts spaced 2 feet apart. Ways of semi-steel, causing all wear to occur in the carriage ways where it does not affect alignment. Bridge of unusual width and depth. Rigid compound rest graduated in degrees. Apron provides double bearing for all pinions and gears. Quick change gear box is a complete unit, with high carbon steel cut gears, providing a wide range of threads and feeds immediately obtainable.

THE PRESENT LULL WILL BE OF SHORT DURATION

The present lull in business affords an excellent opportunity for you to size up your manufacturing equipment and get in ship-shape order for the rush of business, which is bound to come as soon as the present money stringency has been relieved, and international relations settled on a more permanent basis. It also gives the designer and engineer an excellent opportunity for making improvements in design, not only to better the product but to facilitate its manufacture.

Your gear problems can be safely placed in the hands of our engineers —let us help you — no obligations, and

Did You Get Your Copy?

It's worth dollars because it contains the very information which you yourself would gather if you had the time to visit modern heat-treating plants throughout the country. But it costs you nothing, only the coupon, with your name, address, etc.

The cost of compiling and printing has been so great that distribution is limited to those directly interested in heat-treating work or responsible for results. The book is offered gratis in an effort to gauge more fully the value of "Canadian Machinery" as an advertising medium in the heat-treating field.

Please be sure, therefore, to use the coupon.

There's a Better High-Speed Reamer

Your present high speed reamers are undoubtedly as good as the manufacturer knows how to make them—but even the *best* of the old-style high speed reamers are bound to be inferior to

PEERLESS HIGH SPEED REAMERS

(Patented)

"Peerless" High Speed Reamers combine, in a single tool, a hitherto impossible toughness with the unequaled cutting power of modern high speed steel.

Only Peerless *blades* are of high speed steel. Only the blades *should* be of this material. Only the blades do the cutting.

The body requires another specialized steel that will give it the required toughness and life. High speed steel is too brittle for the body.

And the same process that makes "Peerless" a better high speed reamer— tougher, longer lived and less liable to fracture —likewise enables us to produce and sell it more economically.

Send for
"Better High Speed Reaming"
It'll Surprise You.

You Can't See

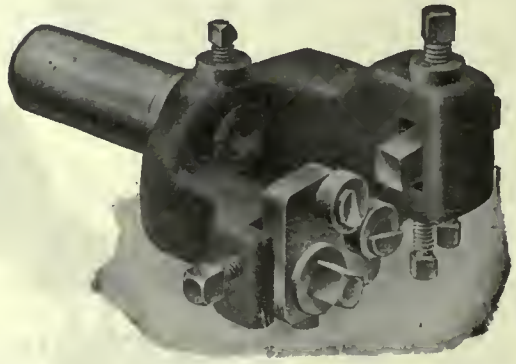
TURRET-LATHE TOOLS & HOLDERS



COMPLETE EQUIPMENT FOR CAPSTAN LATHES FULLY ILLUSTRATED IN OUR TOOL LIST E.

J. ACKWORTHIE LTD.

COLESHILL STREET,
BIRMINGHAM
ENGLAND

"Starrett saws have convinced me they are best, by test. The blade that cuts quicker and lasts longer, cuts labor costs, too."

But for a blade to cut quicker and last longer, it must be the right saw for the material to be cut. Many saws will cut more than one metal. But no saw will cut all metals equally well. The pitch of the blade, for example, varies according to the kind of material cut. Cold-rolled stock and machine steel are cut efficiently with the saw that has 10 teeth to the inch. But brass and soft metals require a fine-tooth blade. And pitch is but one of the things to be considered in selecting the right blade.

To make it possible to select the saw best suited to a particular kind or shape of metal the Starrett Hacksaw Chart was designed. Use it, it will help you cut your cutting costs.

A copy of the chart will be sent free upon request. Send for Catalog No. 22 "3."

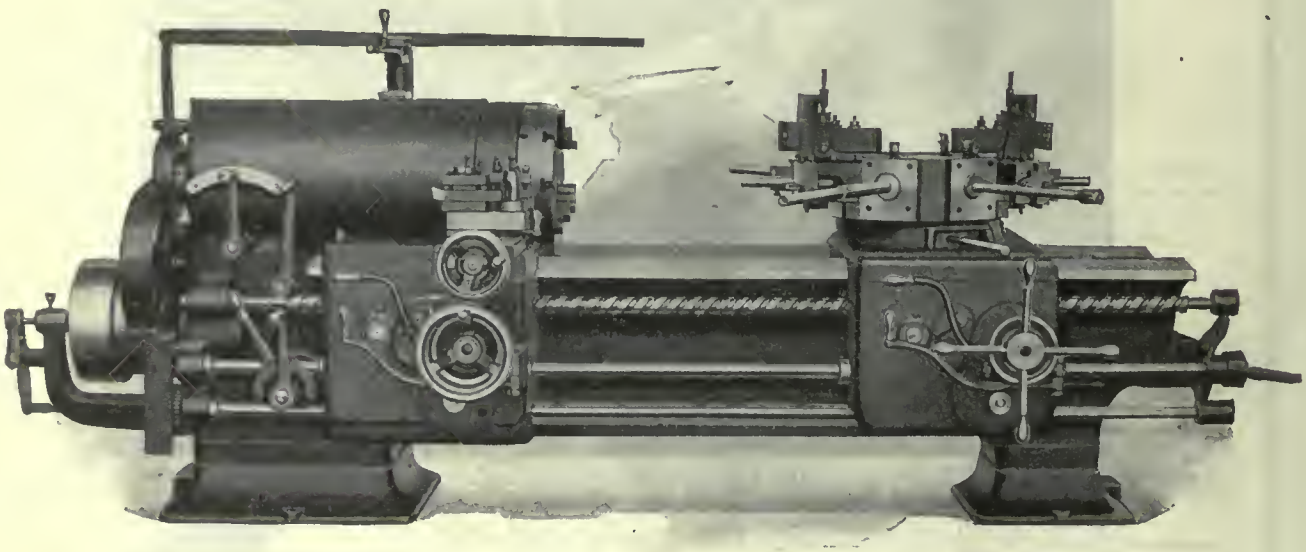
STEINLE



For CHUCKING

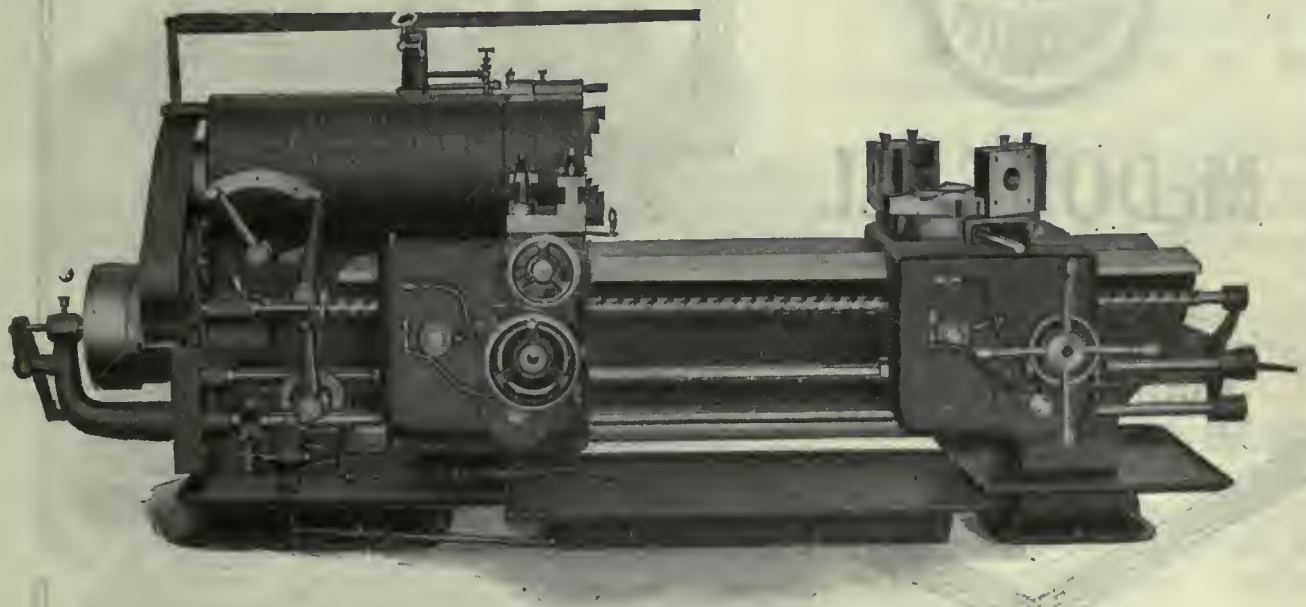
THE Full Swing Side Carriage Turret Lathe is a heavy duty, general purpose machine designed and built to consistently produce duplicate work rapidly, accurately, and economically for manufacturers of trucks, tractors, farm implements, machine tools and a wide range of other industrial equipment.

The general massive construction, the ease of operation of all parts, the single pulley drive and thirty reversible spindle speeds, the rapid power traverse of both carriages, the power cross-feed of side carriage and general adaptability to special tooling equipment enabling satisfactory quantity and quality production—these are strong points well worth considering.

STEINLE TURRET MACHINE CO.

Agents—Machine Tool Engineering Co., Singer Building, New York City; Cadillac Tool Company, Dodge Power Building, Detroit, Michigan; Louis G. Hienes, 75 Fremont St., San Francisco, California, and Title Insurance Building, Los Angeles, California. Foreign—Leo C. Steinle, 53 Victoria St., London, S. W. 1, England.

LATHES



or BAR JOBS

In view of present manufacturing conditions it is invariably performance that counts, and Steinle qualities given above are guarantees of satisfactory performance on your own work.

"If you want a recommendation of our Steinle you can get it from anyone in our organization who has come in contact with its production capabilities," said the general foreman of a manufacturing plant of creamery and dairy machinery and supplies who has had the opportunity of watching its performance since the installation at their plant in 1912.

Similar equipment will do equally well in your own plant.

Why not send us your blue prints if your requirements call for the installation of equipment of this character? We shall be glad to furnish you with production and tooling recommendations, or to have a qualified representative call and take up the question of Steinle methods as applied to your problems.

Go Ahead!

SPEED WHERE IT COUNTS

All set for the signal to go-ahead with speed that counts

Is your Industrial Motor all set to go-ahead? Is every unit of its organization ready to give the speed that counts?

Since 12 per cent. of all manufacturing involves the production of holes the quality of your reaming equipment is of vital importance.

McCROSKY-SUPER Adjustable Reamers

will bring your reaming department through a Long Run test with standard accuracy and maximum production.

The life of one McCrosky-SUPER Reamer exceeds that of a dozen solid reamers. The large range of forward adjustment insures accuracy to the bottom of the last hole. The patented locking device holds the blades as rigid as a solid tool. The toughness of the alloy steel absorbs the shocks of the heaviest jobs.

When you are planning to go-ahead, let McCrosky Catalog No. 8 point the way.

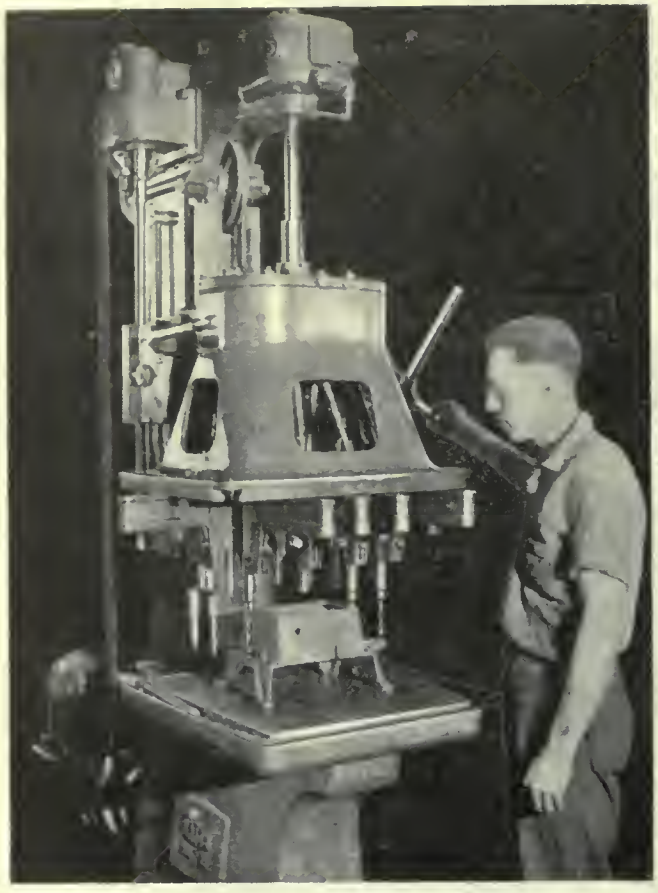
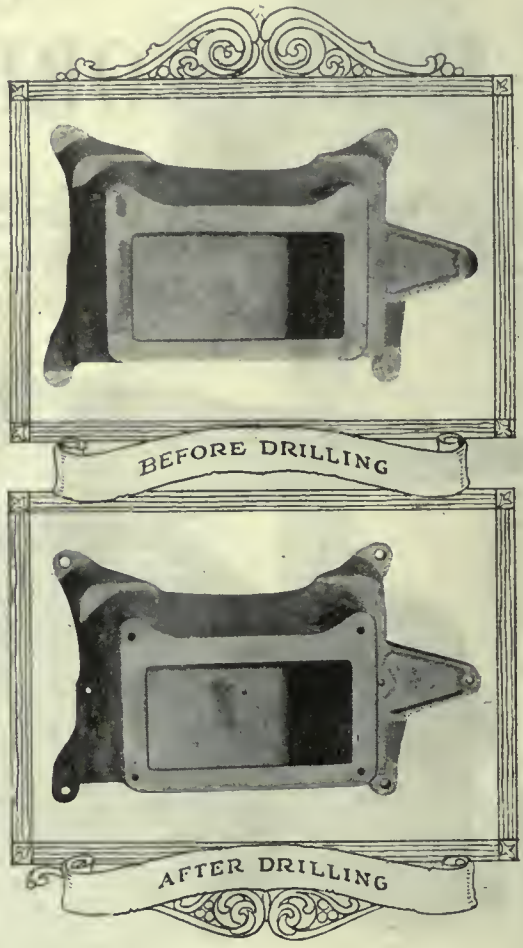
MULTI-DRILLERS NATCO MULTI-TAPPERS





Natco Multi-Driller helps make wash day easier

The Maytag Co., manufacturers of one of the best Washing Machines, use the Natco Multi-Driller to increase production on these labor saving machines.

In the piece shown here, which is the aluminum base for the engine, they drill three holes of different sizes to a depth of 5/8 in. They formerly used a single spindle drill on this job and got a production of 40 per hour. Now, using the *Natco Multi-Driller*, they get a production of 80 per hour.

And yet with this 50% increase in production they have reduced their drill breakage 20% and state that now it is practically zero. But this result is to be expected when you consider the *strictly NATCO Patented Feature* which makes possible an *Independent Change of Speed for each Individual Spindle*. Those not in use are thrown into neutral, saving wear and power.

The *NATCO* is the only Multi-Driller on which you can drill large and small holes, perform different operations, such as drilling, reaming, spot facing, etc., simultaneously and still have each type of tool running at its correct working speed. The independent changes of speed are made easily and quickly while the machine is running.

NATCOS are made in sixteen (16) different sizes, and it does not matter how large or how small the work is, or whether you have one hole or many holes to drill, there is a NATCO that will suit your requirements better and more economically and with greater production than any other Drilling Machine.

We also design and build jigs and fixtures for use in connection with NATCO Multi-Drillers and Multi-Tappers.

Dear Ed..

Passing through our Shop and looking at our battery of Natoo Drilling Machines often reminds me of you, and so many people have expressed their admiration of that part of our Plant, that it has occurred to me you might like to get a photograph of your Machines as installed at our Tipton Works. These Machines are quite a feature in our Plant and are doing most excellent work on our Crankcases for the 11.9 h.p. "Bean" Car.

The photograph is not particularly good but it conveys a fair impression of how the Machines are arranged and it may be of interest to you.

With kindest personal regards and best wishes

Yours very sincerely,

Kitchen and Table Cutlery

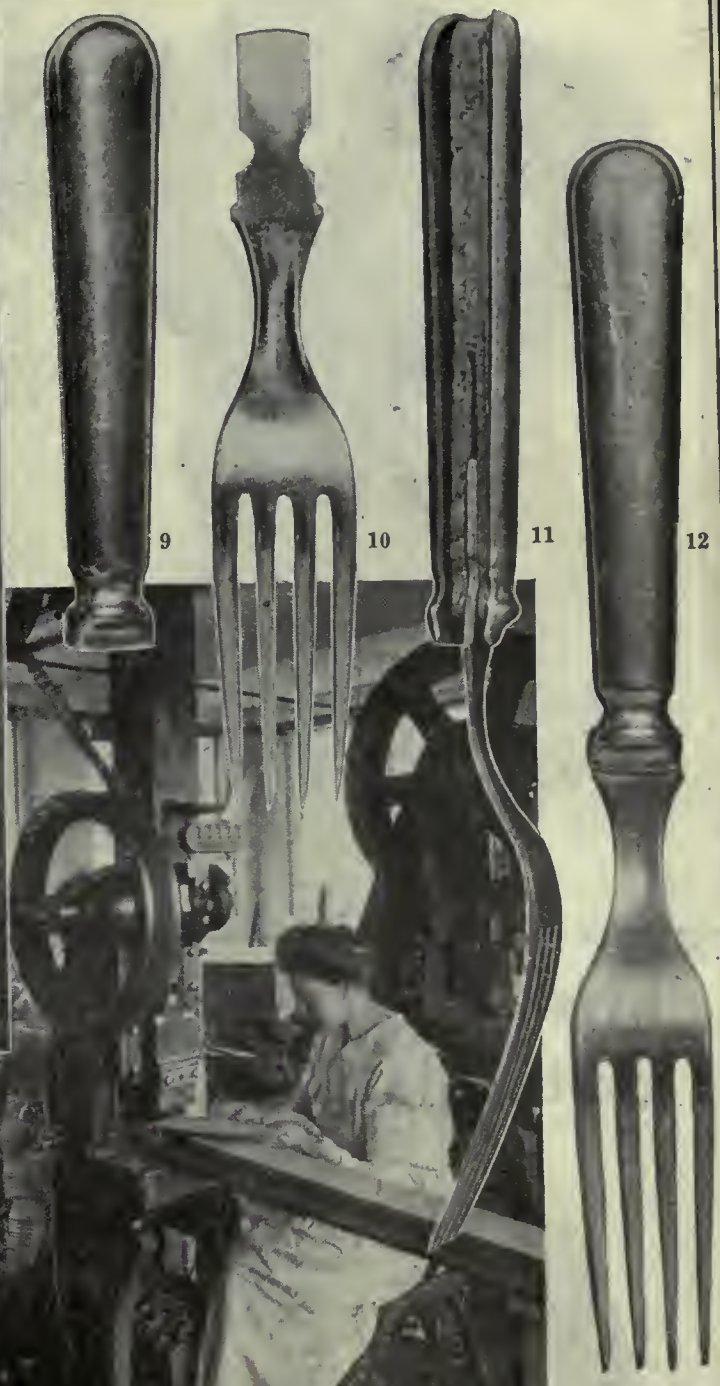
Produced Entirely on "BLISS" Presses

These photographs, taken in the plant of H. C. Hart Manufacturing Company, Unionville, Connecticut, illustrate the method of producing low-priced Kitchen Cutlery in large quantities.

"BLISS" Presses are used for all operations excepting grinding and polishing. The first operation is cutting blanks. Fig. 1 shows blank for handle; Fig. 4, blank for knife blade, and Fig. 5, blank for fork.

The second step is panelling the handles, Fig. 3; the cork filler for the handles is blanked, Fig. 2, and the two successive operations in cutting the fork tines, Figs. 6 and 7.

The final steps are bending, assembling, and closing the handles, illustrated in Figs. 9, 10, 11 and 12.



The photographs of "BLISS" Presses in operation show, on the opposite page, panelling of handles; at the top of this page, assembling and closing, and, at bottom, blanking of cork fillers.

A very high production rate is maintained on these operations—approximately 20,000 per 9-hour day on blanking, 12,000 on panelling, and 5,000 for the assembling and closing. All figures are per machine day.

"BLISS" Presses are adapted to all kinds of Metal Stamping, increasing production and making it more economical.

Little Wheels *for* Big Jobs

IT'S even more necessary to have the right wheels in the tool room than on any other grinding job.

Any old wheel won't do!

Drawing the temper and checking tools is a whole lot more expensive than getting the right wheel.

The proper wheel for your tool room work can be found in our complete stock of Aloxite Wheels.

For reamers, cutters and similar tools the condition is well met with 40 to 60 grit, M to N grade Aloxite wheels. For large, heavy tools we generally recommend 24 to 36 grit, H to I grade.

Let us give you just *the right wheel in the right place*—then standardize on—

4,000 Ton Steam Hydraulic Forging Press for Marine and Other Heavy Forgings.

The product of a modern steam-hydraulic press is denser and more homogeneous than can be obtained with the steam hammer, due to the effect of the blow of the latter not penetrating to the centre, in contradistinction to the uniform kneading effect of the press; while the amount of work that can be done by the latter at one time with little variation in temperature, strongly tends towards a better product. The greater uniformity and reliability of steam hydraulic forgings make their use imperative wherever high-class products are required.

We Will Be Glad to Answer Your Enquiries.

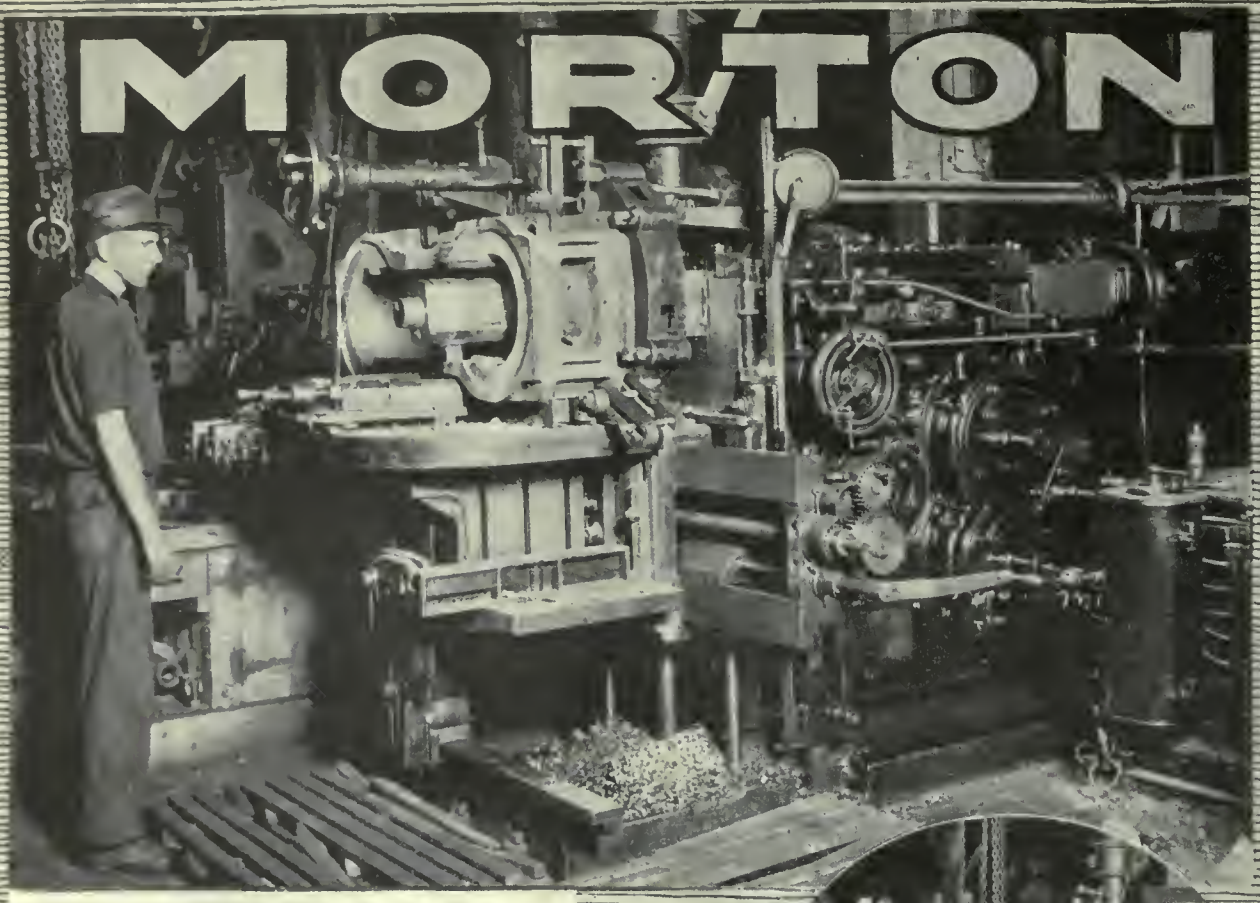
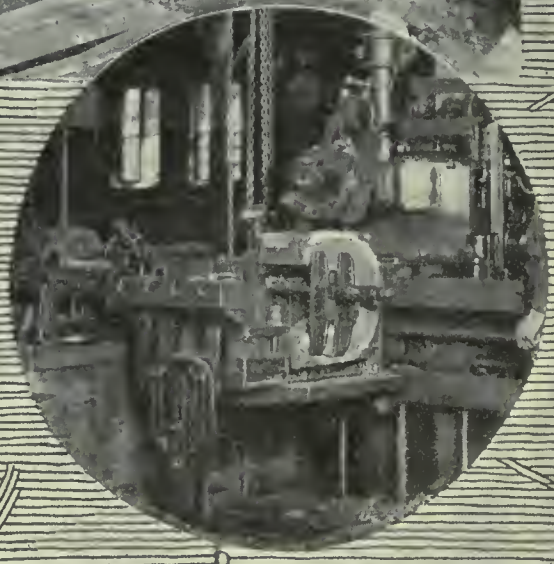
MORTON



Increased Driving Box Repairs Forced the Purchase of this Morton Draw Cut Shaper



Delays to output were traced direct to driving box repairs in this busy shop. Time element and shortage of man power were considered and the installation of this "Morton" reflects the good judgment of these thoughtful officials to install machines of guaranteed production power.

This Morton handles all the machine work on driving boxes—planing to thickness, planing shoe and wedge faces and crowning for bearing brass. It simplifies handling and reduces machine time.

May we send Bulletin A-6 explaining numerous points of merit?

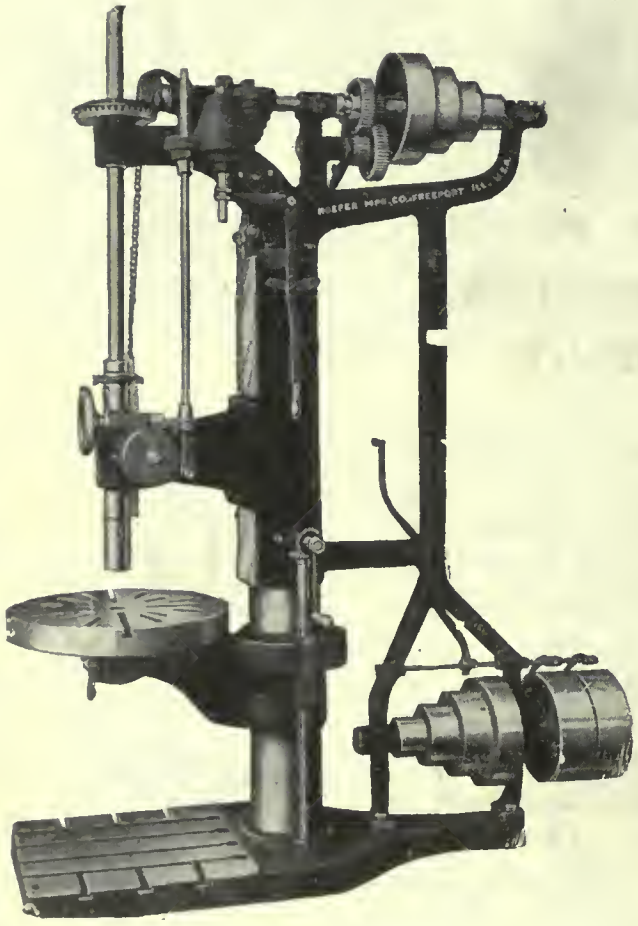
HOEFER

the Driller sold by shopmen



You can talk on an equal footing with a Hoefer Sales Engineer. For he's been all through the very same mill that you are grinding—he's struggled with the problems of planning his production the quickest, best and most economical way, and the harder problem of making performance match promise, and he fully appreciates the importance of selecting equipment that will prove the most suitable to handle a particular set of conditions. So he knows just what you're up against, is qualified to be of real assistance to you and is always ready to apply his own shop experience to help you over a rough spot or two.

We think it a mighty fine combination—Hoefer Drillers and Hoefer Sales Engineers. Drop a line today to the nearest sales office and let a Hoefer engineer prove to your own satisfaction how helpful Hoefer Service and Hoefer Drillers can be to you.

Selecting Wheels for "Off-Hand" Grinding

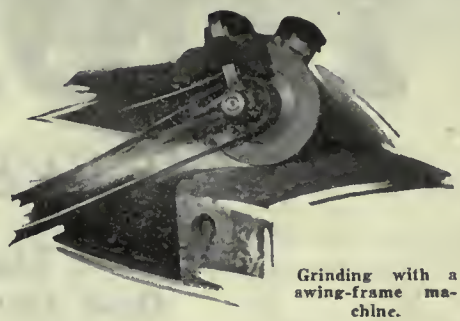
Part only of a treatise on "Grinding Wheel Selection," by Carl F. Dietz, General Sales Manager of Norton Company.

OFF-HAND grinding includes all sorts of rough grinding on castings or other parts where precision is not required, but where the quick removal of metal is the primary object. It also includes certain kinds of tool grinding which depend on the skill of the operator, but is usually confined

Off-hand grinding on a floor stand.

to the rougher tools for lathes and planers. There are three types of machines employed: Floor and bench stands, swing frame, and flexible shaft machines. Obviously the floor stand, being generally the most rigid of these types, may for certain operations be fitted with comparatively soft wheels. For various kinds of tool grinding or light general work, grades M to P can well be employed, while for heavy castings such as journal boxes and the like, or very sharp work, grades as hard as U are necessary.

Swing frame machines are subject to much vibration, due to their light construction and also to the manner of application. In grinding with swing frame machines the wheels are generally subject to much abuse, being brought down upon the casting with much force. Vibrations transmitted as a rapidly intermittent series of shocks at the wheel face can readily be seen to exercise a destructive influence on the structure. Grain particles are split off before they have performed their measure of



Grinding with a swing-frame machine.

work unless they are firmly held; hence, harder grades must be selected.

The flexible shaft machine is not much used, but finds application where the parts to be ground are clumsy and have corners or recesses that can only be reached by having a wheel so mounted that it can be presented to the work by the operator at will. Bath tubs, sinks, certain railway castings, and the

Flexible shaft equipped with Norton wheel.

like are ground in this manner. Obviously with little to support and only the hand of the operator to guide or steady it, the wheel has to overcome the shocks resulting from the many irregularities of surface ground and therefore needs to be of hard grade.

VOL. XXIV. No. 27 December 30, 1920

1921 Finds Canadian Business Sound

THE words deflation of values and readjustment are so threadbare from overwork that they have lost their power to convey the meaning they should express.

Our best business men saw readjustment coming as soon as the war was over. Steps were taken then to fight it off—to continue our fake prosperity—and these were successful to a much greater degree than the most ardent exponents of that system ever thought possible.

Nothing cracked following the war.

We continued to imagine that our dollar was one hundred cents, and not merely a medium of exchange, depending for its value on the selling price of commodities.

The deluge of war work brought with it habits of waste—an unbalanced organization with all stress on production and none at all on selling—a government ready to take the product and assist in financing its production led to a neglect of scientific market surveys and study.

Men and women from all trades and callings went to war shops and earned more money than they ever thought possible. They acquired habits of extravagance in living and lavishness in spending that read like new ventures of the prodigal son.

In plain, honest words—we were not ready to settle down after the war, and the volume of business that has passed since then has too often lacked the sincerity that springs from intrinsic value and the stability that can be secured only from sound basic conditions.

Readjustment is bound to hurt. It would be against all business and physical laws were it otherwise.

It means passing from an atmosphere of imaginary prosperity down to an era of common sense.

It means that earnings must be less, where there was war inflation—it means that competition is again taking its old place in the business world, and that sales will more and more rest, not upon emergency or undue haste, but upon mechanical excellence and administrative sincerity.

Labor efficiency is increasing, but the lamentable, grotesque feature is that the improvement comes when the demand for production has fallen off.

There has been progress made in killing the strike germ.

Workmen seem slow to realize what a costly weapon the strike has been to labor. It has not been a boom, but a boomerang.

The year 1921 will require patience and consideration from employers and employees. It would be a wonderful thing were the labor agitator and the autocratic employer to link arms and depart from the industrial district. Their absence would be of more assistance than their presence and interference.

Fundamentally Canadian business is sound, and becoming schooled to changed conditions. Financial restrictions have caused firms to cut off the frills and clean their houses, and they have put them in shape for healthy growth and certain expansion.

Scores of splendid American firms have decided on their location in Canada, and from here will cater to the great markets of the Empire.

The development of the Canadian West is going on on a more sane basis than ever before. The people there realize that their future rests in working the soil instead of the people. This means more implements. More implements means more machine tools, iron, steel and equipment.

The year 1921 is before you, and it comes a day at a time. If you think there's a greater or a better land than Canada, or a place where you will be better treated, make haste and locate—if you believe that this great Canada is your best chance, then help make it what you want it to be.

Tracing the *Development* of the Year

Canadian Cities Have Prospered, and, in Spite of High Costs, Extensions Have Been Made—Many U. S. Firms Getting Ready To Open Up New Branches in Canada During the Year 1921.

CALGARY HAS HAD A BUSY YEAR

Reports Say That Business Has Been Good In All Lines—Work Still On in the Oil Fields in That District

By J. H. HANNA, Secretary Calgary Board of Trade

CALGARY.—During the past year Calgary has enjoyed increasing prosperity and this is shown in the bank clearings, which for the first ten months of the year were $348,549,415, as compared with $269,839,671 for 1919, an increase of $78,709,744. The live stock industry is one of the important branches of Calgary's trade and during the past year the Alberta Stock Yards Company have spent $400,000 in improvements and additions to the yards and for new offices. They have also secured an additional sixty acres of land in order to increase their facilities, and provide for the rapidly growing business.

Notwithstanding the comparative high cost of building, considerable work has been done and the building permits for the first ten months of the year show a total of $2,532,200, an increase of $411,200 over the previous year. At the present time two large and modern picture theatres are under construction and will doubtless be completed in the course of the next couple of months.

In order to keep pace with the increasing population, it has been necessary for the School Board to build five new schools, and even that extra accommodation has not been quite aufficient to meet the need.

Calgary has also benefited by the increased output of coal in this part of the Province, most of the leading coal mining companies having their head offices in this city. In the Drumheller district particularly, there has been a greatly increased optput of coal, due to the new markets obtained in Manitoba and Saskatchewan. There is every prospect that this trade will develop, in view of the tests which have been made and which have proved satisfactory. This will mean a greatly increased output for the Alberta mines in future.

Calgary's principal industries, including packing house products, flour, breakfast foods, soap, saddlery, and other commodities, also the large shops of the C. P. R., have been kept busy during the year, although latterly, owing to the readjustment in prices which is now going on, business is not quite as active as in the earlier part of the year.

Development work is still going on in the oil fields adjacent to the city, and operators are hopeful of finding further oil deposits in the near future.

ST. JOHN HAS MORE POWER NOW

Existing Plants Have Been Much Enlarged, And Shipping Facilities Are Being Improved for Ocean Ports

By R. E. ARMSTRONG, Secretary St. John Board of Trade

ST. JOHN, N.B.—Marked progress has been made along one important line of industrial activity on this locality during the past year, viz., the dry dock and port development at Courtenay Bay, East St. John. The chief purposes of this development are to provide St. John with additional port facilities, supply it with one of the largest dry docks in the world, and at the same time furnish the Canadian National Railways with adequate terminals. The C. N. R. has had for many years track connection with the western side of Courtenay Bay and recently the eastern side has been connected with the main line of the C. N. R. by means of a spur track. The inner basin of the bay is being dredged out to conform to the depth of the main harbor which lies westward of the peninsula upon which the city proper stands.

Adjacent to Courtenay Bay, further industrial promotion is about to be developed, including the establishment of a mill for the manufacture of fibre cases and also a pulp mill. These industrial works will be established by a corporation, of which the principals are the Clarke Bros. firm of Bear River, N.S.

The pulp mill of the Nashwaak Pulp and Paper Company, located alongside the reversing falls, just above the main harbor, has been enlarging its capacity lately and has arranged for an added water supply from the city to cover its new development programme.

Immediately adjacent to this mill the Canadian Pacific Railway is engaged in the construction of a steel bridge across the Falls. The piers for the bridge are well advanced and the placing of the metal work will be begun within the next few months.

The lime industry of St. John has made excellent progress this year. The plant of the Provincial Lime Company, which was destroyed by fire some months ago, has been rebuilt and enlarged, and adjacent to it the Provincial Government has an agricultural lime industry at work.

The lumber industry, insofar as the overseas trade is concerned, has been quiet this year, chiefly because of the unsettled conditions in the Mother Country. Large quantities of lumber are piled up here, awaiting an improvement in the market conditions. A somewhat better state of affairs prevails in the United States lumber market. The shipments of lumber to the United States during the first nine months of 1920 amounted to $3,737,-992, as compared with $1,506,897, for the same period of 1919. The entire lumber export to the United States last year from this district was valued at $2,504,798. Almost all the lumber mills are now closed down for the season. It is not expected that there will be a large lumber cut this winter.

There have been a few changes in the metal industries. The Portland Rolling Mills plant on the Strait Shore has lately changed hands, and the company now operating it is known as the New Brunswick Rolling Mills. A number of lines of iron and steel products are being manufactured by this Company.

The foundry on Courtenay Street, known as the Smith Foundry, has been acquired by the firm of Harrigan and Howard, who are operating it as the Courtenay Iron and Brass Works.

The McAvity foundry plant on the Marsh Road is not yet operating to capacity, but the city plants of this energetic firm are very busy.

The Maritime Nail plant, the Pender Nail Works and the Canada Nail and Wire Company have been fairly busy throughout the year.

There has been a merger of the edge tool works formerly operated by Wilfred Campbell & Son and Josiah Fowler Co., Ltd. The new corporation operates under the firm title of Campbell & Fowler.

The brush and broom factory of T. S. Simms Co., Ltd., has been operating to full capacity, necessitating some important additions to the plant. The Simms plant is one of the best in Canada.. The factory of the Canada Brush Company has also had a good season's work and

some improvements are being outlined for the coming season.

The year has been a quiet one among the fish industries, due to scarcity of fish and disturbed market conditions. The sardine plant of the Booth Fisheries Company, of Canada, has not opened at all this year. The Connors Bros. sardine factory had a fairly good season, but with most of the fish plants the season has been a far from satisfactory one.

One of the largest of the city's industrial plants—the Atlantic Sugar Refinery—has been one of the greatest sufferers from the sudden drop in sugar prices. This factory had been doing a capacity business until a few months ago and had found it necessary to expend a quarter of a million dollars or more in additions and improvements to its storage facilities. The suspension of its business a few weeks ago has not only forced hundreds of men out of employment, but it has also greatly added to the storage troubles of the Company. In addition to its own warehouses being filled with raw sugar, several city warehouses on the water front are crowded with the raw article. It is expected that the refinery will resume operations about the first of January.

The port industrial workers have not been overworked this season and, unless an improvement in the overseas markets occurs very quickly, the amount of freight passing through the port will not be as large as usual. The shipments of lumber and general cargo threaten to be light this winter. The shipping merchants are optimistic and are hoping for better things by the first of the year.

Since last winter an additional grain conveyor, in connection with the C.P.R. grain elevator, has been placed on one of the west side piers.

One of the most encouraging features of the industrial outlook in this vicinity is the development of Hydro-Electric power, which has just been begun under provincial auspices on the Musquash River, 12 miles from St. John. From this one source about 8,000 horsepower will be developed for industrial and general use in the city. With cheaper power added to the export possibilities and distributing advantages of St. John, the industrial outlook is most encouraging.

In closing, a word or two concerning city industrial development. This year, for the first time since the close of the war, the city has been indulging in an extended programme of street paving, killing two birds with one stone—beautifying the city and at the same time furnishing employment for returned soldiers and others out of work. The programme will be revived in the spring. It is intended during this winter to indulge in some road extensions at the farther end of the city, adjacent to the Kennebecasis river, where the city owns a beautiful natural park that was bequeathed to it by a former federal member, Colonel Tucker. The city also proposes to do a lot of stone crushing this winter to help out next season's street programme.

THREE RIVERS HAS NEW PLANTS

Big Building Programme is Being Finished—An Active Board of Trade is Working on Several Schemes There Now

By WILLIAM TROTHIER, Assistant Field Secretary Three Rivers Board of Trade

THREE RIVERS, QUEBEC.—Three Rivers, in the Province of Quebec has, this year, more than maintained its rapid growth of the last ten years.

Industrially it has taken a long step forward, with the coming of a new plant, the Three Rivers Pulp and Paper Co. The capitalization of this latter company is set at $4,400,000. It has contracted for a plant costing a million and a half, which, when completed, will employ approximately 5,000 men and have a capacity of 200 tons daily.

Three plants, the Canada Iron Foundry, the Wayagamack Paper Co. and the St. Maurice Paper Co. have opened club-houses for the workmen, showing a healthy development of the spirit of brotherhood between capital and labor.

Few strikes have disturbed the industry field. Wages are moderate, the workers satisfied.

The problems that affect the city, such as a good water supply, housing, a new station and new transportation facilities to meet the growing demands of business, are all on the coming year's program of the reorganized Board of Trade, which starts the new year with a revenue from memberships exceeding anything it has had in its history.

Plans ready for the building of the million and a half dollar plant of the Three Rivers Pulp and Paper Co., capital, $4,400,000. Capacity, 200 tons per day; employs 5,000 hands.

Plans ready for a million dollar addition to the Wabasso Cotton Co., making increase of $200,000 in payroll.

Tidewater Ship Co. notes big increase in business.

Mechanical Engineering Co. buys 365,000 feet of land for expansion purposes.

St. Maurice Lumber Co. completing new mill for paper manufacture. Will be ready to manufacture pulp in the spring. Will probably require 5,000 hands in new venture. This company has also spent $50,000 in the construction of homes for workmen.

The Canadian Consolidated Rubber Co. has opened a branch in this city.

A steel concern is negotiating with the city for a plant in Three Rivers.

Other developments indirectly affecting the industrial progress of the city is the building of a bridge at Batiscan, which will greatly facilitate transportation here, and the opening of industrial classes for workmen.

NEW INDUSTRIES IN WOODSTOCK

And a Very Large Number of the Men in Factories Own Their Own Homes—Look for a Good Year

By HARRY SYKES, Secretary Woodstock Board of Trade

WOODSTOCK, ONT.—Woodstock has experienced a busy year in almost all lines of industry. A review of the labor situation in Woodstock reveals the pleasing fact that there is little unemployment in the city at the present time. While some of the local factories have reduced their working hours during this month, none of them have closed down, and only a small proportion have reduced their staff to any extent. A large programme of city improvements is under way, which is helping materially to solve the labor problem and the volume of work thus made available appears to be nearly equal to the demand.

Twenty-three principal industries represent a total investment of $4,430,000. The output of these industries during the past twelve months was $8,418,000. The annual payroll amounts to $1,797,000. It is a matter of congratulation to the factory employees that 534 own their own homes, which are valued at $720,000.

During the past year a Canadian Branch of the De Long Hook and Eye Company was established here. Also the Kennedy Car Liner and Bag Company purchased the William Stone Company factory. The newly organized Karn Piano Company commenced operations in the Karn Factory. A few days ago arrangements were completed with the American Ironing Machine Company, Chicago, to establish their Canadian branch in Woodstock. They anticipate operating their plant here about March 1st, and will make Woodstock their head office for Canada.

The heads of industries are quite optimistic as to the future, and are looking forward to the factories being busy as usual in a short time.

ST. THOMAS' INDUSTRIAL ERA

Plan to Buy Tract of Land for Firms That are Likely to Come—Several New Ones Came in 1920

By J. L. LODGE, Secretary St. Thomas Board of Trade

ST. THOMAS, ONT.—The Thos. A. Edison, Inc., have purchased the plant and buildings of the St. Thomas Cabinets Limited, comprising about one hundred thousand feet floor space, to which they will add two large wings next year, and this company, which will be known as the Canadian Edison Phonographs, Limited, will begin operations about the first of the year.

Hutch Bros., of Canada, manufacturers of wooden vehicle toys, and the Universal wallpaper hanger, and the Provincial Machine and Supply Co., manufacturers of phonograph hardware, were incorporated about the first of the year, and are now both under production.

The E. T. Wright Co., manufacturers of "Just Wright" shoes have disposed of their plant and business to the Talbot Shoe Co., Limited..

The Canada Iron Foundries have spent $150,000.00 in extending their plant this year, and anticipate further extensions in 1921.

Early in January the citizens will vote on a by-law providing for the purchase of 75 acres in the east end of the city for the purpose of an industrial area. The proposed area is bounded by the Michigan Central, Canadian Pacific, Wabash, and Grand Trunk Railways.

KITCHENER CONTINUES TO GROW

There Are Now 123 Industries With a Payroll Of $11,000,000—Large Extensions Made to Factories

By E. J. PAYSON, Secretary Kitchener Board of Trade

KITCHENER, ONT.—Kitchener continued during 1920 to experience a steady expansion and prosperity of established industries. Population increased by 1,975, and in the city proper there are now 23,027 people. Assessable property increased by $3,265,344, and now stands at $18,053,251. There are 123 industrial establishments in the city, giving profitable and steady employment to some 8,000 employees, who receive about $11,000,000 in wages. The aggregate output of manufactured goods last year was approximately $40,000,000.

Among the larger additions to industrial plants is that of the Lang Tanning Company, Limited, who are spending about $200,000 on buildings and equipment. The Kaufman Rubber Company, Limited, has under erection a five story addition to its big factory, which addition would make a substantial industry of itself. The Dominion Tire Company, Limited, has erected building and equipment the present year which, when completed, will have cost nearly half a million dollars, and their daily output of automobile tires and allied products has reached mammoth proportions.

The Ames-Holden McCready System completed this year the automobile tire factory begun late last year, and will shortly have reached the quantity production stage in that line. This firm has built and equipped this year a factory for the production of felt footwear, which is running to capacity. They also have begun to manufacture rubber footwear in premises in their tire factory not yet occupied by that industry. This trio of industries under the A.H.M. control form a big and valuable addition to Kitchener's manufacturing interests.

Salts & Potash, Limited, have doubled the space and capacity of their plant and are approximating the dimensions of a large and important industry. Their products consist of salts, potash, chlorides and other chemical products.

To cope with the increased demand for electrical power the Light Commissioner has erected a modern equipped sub-station in the industrial centre of the city. Transportation has been improved by the construction by the C.P.R. of a special freight line entering the city at the east end as a continuation of the Grand River Railway, which is the electrically operated branch of the C.P.R. between here and Port Dover, on Lake Erie.

The addition to Victoria school was completed and occupied this year and at present a big extension is being erected to the King Edward school, and a wholly new school is being built in the South Ward.

This year has also seen the building and equipment of a Nurses' Home for Victoria Hospital, built, furnished and presented to the hospital by the late Jacob Kaufman and family.

BRANDON GETS BIG CONCERNS

Gaining in Importance As a Distributing Centre—They Look for Many More In Coming Years

By H. L. CRAWFORD, Brandon Board of Trade

BRANDON, MAN.—Brandon's importance as a distributing centre is being recognized more and more each year. The number of large concerns locating here established a record during 1920, that has not been equalled since the palmiest days before the Great War.

Some of the really large concerns that have now located here are the Massey-Harris Company, Limited, and the Imperial Oil Company. The Massey-Harris people bought the Gordon Mackay building for $130,000, and will establish a large distributing plant for Western Canada here.

The Imperial Oil Company has commenced operations to erect a $350,000 plant here, and their offices are already established in the city. The L. R. Steel Company has recently made a purchase of a large business in this city, and will open up January 1st. It is also stated that the Grain Growers Limited will place a large plant here for distribution purposes in the West. Several other smaller concerns have located here during the year, and the prospects for a large number of manufacturing plants coming here in 1921 are very bright.

CHATHAM SECURED TWO IN 1920

Industries Have Been Well Employed and Plans Are Being Made for Full Operations in Short Time

By M. M. MAXWELL, Manager Chatham Chamber of Commerce

CHATHAM, ONT.—During the year 1920, Chatham has located two industries, one of which moved here from another town, and the other, a new Canadian corporation, in which American interests are largely concerned. The first company is making knit goods, while the latter is putting on the market a new furnace, modelled after a very popular and wide selling furnace in United States. Locally, conditions have been very good during the year, and the majority of concerns have extended their businesses considerably.

The Hayes Wheel Co. are extending their rear axle assembly department, as well as their truck wheel section; the Canadian Fertilizer Co. have added quite an extensive addition to their building, making commercial fertilizer; the Gray Dort Motors Ltd., have added a large plant, in which they have installed extensive and modern machinery for making some of the parts which originally were made in other plants, particularly the pressed steel parts; the Libby, McNeil & Libby Co., canners and packers, have added to their buildings during the year, while the Canadian Des Moines Steel Co., making structural steel and tanks, have a considerable addition under way; the Chatham Malleable and Steel Co. is constructing a building which practically doubles their capacity

and installing their late, modern machinery for the manufacture of automobile accessories.

Other industries in the city are doing some small extension work, while in one or two cases considerable expansion is now planned, but actual construction work has not been undertaken and will not be for a few weeks or possibly six months.

The city of Chatham has not experienced as much of a commercial and industrial slump as has been experienced in many cities, because of the varied nature of the industries located here. There are very few idle men at the present time, even when other cities are experiencing considerable difficulty in this particular connection. Two plants in the city have been running small force for some weeks, but both are now making preparations for reopening their plant to full capacity by the first of the year at the latest.

BIG PLANTS PUT UP IN OSHAWA

General Motors Added to Their Plant—Several Large Buildings in the Course of Construction

By J. A. McGIBBON, Secretary Oshawa Board of Trade

OSHAWA, ONT.—During the past year Oshawa has made wonderful steps in industrial development. General Motors have added considerably to their plant, which now includes the Oldsmobile Motor Co., in addition to the McLaughlin and Chevrolet plants and the Samson Tractor. Pedlar People have moved into their spacious new plant, one of the finest in the province. W. J. Trich & Co. are rebuilding their planing mill and woodworking factory.

The Moffatt Motor Sales have erected a fine new showroom for the display of their Oldsmobile cars. The new Theatre Paramount has opened a fine, up-to-date structure seating 1,100 people. L. R. Steel & Co. will move into their new store in a few days. Ward & Dewland, dry goods merchants, are moving into a fine new store erected by Bradley Brothers. A 65-acre park was given to the town this year by General Motors Ltd.

WINNIPEG IS GROWING RAPIDLY

Building of Factories and Shops Calls for Expenditure of Many Millions—More Power to be Available

By J. M. DAVIDSON, Winnipeg Board of Trade

WINNIPEG.—The year 1920 has seen substantial progress in the city of Winnipeg. Building figures for the year will run close to eight and a half million dollars. Not only is this the largest total since 1915, but it equals the combined figures of 1917, 1918 and 1919. Winnipeg's building totals for the first nine months of 1920 were equal to the combined totals of twenty other Canadian cities. Three large motion picture theatres have been erected in Winnipeg during the year, and operations have just been commenced on a six story addition to the Opympia Hotel.

Bank clearings have shown a remarkable increase during the year. For a single week ending November 10th, clearings reached the enormous total of $110,806,-325.00. This is not only the highest weekly figure ever reached in the Winnipeg clearing house, but it actually exceeded the clearings of the City of Toronto of two weeks previous.

The total capitalization of new companies established in the Province of Manitoba has already exceeded one hundred million dollars. Some of the larger industries established in Winnipeg during the year are: The Canadian Community Cut Glass Co.; Red River Pulp & Paper Co.; Western Film Mfg. Co.; Orange Crush Bottling Co., soft drinks; Tractioneer's Ltd., farm implements; Western Suit Case Mfg. Co.; Canada Fibre Products Co., hemp products; Winnipeg Motor Cars Ltd., automobile manufacturers; Picardy Candy Shops, Ltd.; Crown Broom Mfg. Co.; Martin's Limited, clothing manufacturers; Campbell Mfg. Co., clothing manufacturers.

The Winnipeg River Power Company, a subsidiary of the Winnipeg Electric Railway Co., has worked during the year on the first unit of a $10,000,000 power plant on the Winnipeg river.

U. S. PLANTS IN STRATFORD

Two Have Started and Already Have Secured Production—Employment For Many More Hands is Provided

By A. W. DEACON, Secretary Stratford Chamber of Commerce

STRATFORD—In the past year the Canadian Edison Appliance Co., Ltd., and the Gerlach-Barklow Co., Ltd., both American plants, opened up Canadian branches in this city. The former manufacture all sorts of electrical appliances and is employing approximately three hundred hands. The Gerlach-Barklow Co., Ltd., manufacture high-class art calendars.

The Kindel Bed Co., Ltd., which opened its Canadian branch in Stratford about two years ago, have, during the past few months, largely increased their plant. The Grosch Felt Shoe Co. have commenced operations during the past year, manufacturing felt shoes and are now employing approximately seventy-five hands.

NEW PLATE MILL AT SYDNEY

Development of the Steel Mill Has Been Carried On—Making Several More of Its Own Products Now

By F. C. KIMBER, Secretary Sydney Board of Trade

SYDNEY, N.S.—In February, 1920, the new 110" plate rolling mill of the Dominion Steel Co. was placed in operation. This new department involved an expenditure of approximately $5,000,000 and has a capacity of approximately 12,000 gross tons monthly of sheared plates up to 98" in width. Since the beginning of operations it has been shipping its entire production to the Canadian Government, with which the company has a contract for from 50,000 to 75,000 tons of plates per year for five years. In the early part of the year the first two units were placed in operation in the company's new power house, which has been erected at a cost of $1,250,000 and which, when completed early next year, will have a maximum capacity of approximately 10,000 W.W. This additional power will permit the electrification of some of the producing departments that have heretofore been using steam, and will enable the company to produce its electric power requirements at the lowest possible cost per K.W.H.

About two years ago the company completed an installation of 120 latest type Koppers by-product coke ovens with all auxiliary apparatus. This installation proved entirely satisfactory. A contract was let for another two batteries of thirty ovens each, which it is expected will be in operation about March 31st, 1921.

During June, 1920, the new electric drive for the rail mill was placed in operation and it has since given entire satisfaction. This replaces the former expensive drive in this department and the additional electric power required is made possible by the erection of the new power house above referred to.

Prior to the end of the year the company should have in operation its new plant for the production of silica brick. This will have a capacity of about 15,000 9" straights daily. After experimental stages have passed it should enable the company to discontinue purchasing a large part of its silica brick requirements from Pittsburgh district. The silica rock required in this new department is to be brought from a quarry situated only fourteen miles from the steel works.

During September, 1920, the company reopened an old

plant which had been discontinued some years ago by other parties and commenced the production of cement from blast furnace slag. The resulting product has been found to be quite satisfactory for the company's purposes and this department is now operating at the rate of about three hundred barrels per day.

It is reported that the Cross Fertilizer Co., Ltd., which manufactures fertilizer from the Dominion Steel Co.'s slag, and which has built up a very successful business in this very essential product, is contemplating an extension of its plant and producing capacity in the near future.

BORDER CITIES GET U. S. PLANTS

In Negotiation With Large Number of These—Many Will Come Over as Soon as Building is Reasonable

By F. MACLURE SCLANDERS, Border Chamber of Commerce, Windsor

BORDER CITIES—Ford, Walkerville, Windsor, Sandwich, Ojibway. During the past year thirty-one new industries have located at the Border Cities, so that they now have 206 of such, large and small. During 1919, forty-four new manufacturing concerns came in. Practically all of such industrial development emanates from the United States.

At present, we are negotiating with no fewer than seventy-six American concerns, over a third of which have already intimated their decision to come here whenever conditions are more stable. In addition, we are working upon other eighty-six prospects which are shaping favorably in most cases, but are still in the preliminary stages and not yet in the "live" class which embraces the seventy-six first mentioned.

In view of the foregoing, we have obvious reason for encouragement. As a matter of fact, the truly extraordinary development characteristic of these Border Cities during the past few years is still largely unrecognized or uncomprehended in centres further east. This may be because our development mostly has its source in the United States. At any rate, we at this southernmost corner of Canada are forging ahead in a sense that is literally phenomenal. Ours is not mere development. It is transformation. Within the lifetime of a child now at kindergarten we have simply leaped from the town category into the truly metropolitan. This statement is at once conservative and perfectly safe—for, its truth may be demonstrated by the evidence of one's own eyes. It is visible on every hand; in street after street of new homes; in new factories and business premises of every description, and in a prosperous population which now approaches the 60,000 mark! Indeed, one is vividly reminded of the Western boom period of 1910-12, and of the wondrous strides then made by certain more progressive prairie centres. However, there is one fundamental difference: our progress and expansion are built upon the most solid of all foundations—the location and successful operation of new industries.

It may interest to remark that the growth of our industrial life owed practically nothing to munition or other war work, very little of which was conducted here. Few war orders came our direction. Consequently, we pursued the peaceful tenor of our productive ways; and in the end it is probable that we gained rather than lost, even although there might have been some disappointment at the time. Others got the war orders; and while they were working thereon we were expanding the production of our normal commodities.

As to the situation and outlook, we are conscious of no logical reason for gloom. Rather do we welcome the present lull as the one circumstance absolutely required to restore general conditions to the more nearly normal and thereby stimulate a safer and more substantial business than ever.

In our opinion, prices and production costs are grotesquely hysterical. They are idiotic. They are also impossible. They have killed commerce. At last, people have torn the war bandage from their eyes. No war haze clouds their vision. Things appear at their true value. Buyers are disillusioned. The $35 suit that may now be purchased for $120 appeals as a stupid impertinence. The $35 home which its owner is willing to rent at $80 no longer attracts; the $6,000 which offers at from $17,000 to $20,000 still further accentuates the crass absurdity of the greediest, craziest period in the world's history.

Fortunately, however, the crisis is over; the fever diminishes. The candle of high costs is now brightly burning at both ends. Material costs have already indicated a marked decrease while a remarkable increase characterizes the production of the individual worker. We have now actually entered upon the first real period of readjustment. It took us quite a time to wrestle with the purely preliminary stages thereof. Now we are about to make real progress.

As it is, however, American and other manufacturers flatly state that they won't build factories at the prices of to-day which, in the comparatively near to-morrow, must be much lower. Some of them will come in immediately, provided they can be suitably accommodated in rented, ready-made premises.

The outrageous prices of to-day constitute an almost insuperable obstacle against the further, fullest industrial development of this country. But, whenever such revert to the more nearly normal, all the pent up progress of months will be let loose upon us. Business will be better than ever, in our opinion; because business will then be safer.

We do not look for a violent depression: but rather a swift and comparatively easy reversion to a truer basis. Of course, even such a process involves loss for many. Nevertheless, past years of good business, wonderful business, should place intelligent business men in a position to take their goats along with their sheep.

Upon the whole, we were never more optimistic; and, even while waiting for more normal times, we are doing wonderfully.

BIG THINGS AT PORT ARTHUR

Pulp and Paper Industry is Becoming an Important One—Plenty of Power Available For Use There

By M. FRANCIS, Secretary-Treasurer Port Arthur Board of Trade

RECENT expansions industrially are the inclusion of manufacturing pulp and paper and mining machinery, in the operations of the Port Arthur Shipbuilding Company, Ltd., which will mean an increase of approximately 600 skilled employees, and erecting an open hearth furnace, also the building of the Kaministiquia Pulp & Paper Co., Ltd.'s new pulp mill. It is understood that the local branch of the Provincial Paper Mills, Ltd., is about ready to increase its output to 100 tons pulp and 50 newsprint, per day. Plans for two other pulp and paper mills are about completed.

During the year the Port Arthur Wagon Works has become the property of Jno. Stirrett & Sons, who are expanding into a general woodworking business.

While many manufacturing centres have been hampered by lack of Hydro-Electric energy, Port Arthur is in the fortunate position of having supplies adequate to take care of considerable industrial expansion. The development in the Nipigon river at 72,000 h.p. places Port Arthur in a very enviable position.

The city has set aside for incoming industries 1,000 acres of favorably situated land served by both transcontinental railways and harbor.

Port Arthur is also extremely fortunate in being surrounded with a country that offers unlimited recreational and vocational facilities. These attract each summer many thousands of tourists, 32,000 in 1920, and this is rapidly becoming one of the community's chief industries.

ADDITIONS TO THE GALT SHOPS

C. P. R. Spending Large Amount For New Service There—New Companies Enter The Shoe Manufacturing Field

By H. J. FOSTER, Secretary Galt Board of Trade

GALT.—The industrial development of Galt during 1920 has, on the whole, considering the almost prohibitive building costs, been very satisfactory. Our machine shops, until recent weeks, have been very busy, and a few additions have been made, the R. McDougall Company leading in this respect.

Two new shoe factories, Scroggins Brothers, and the Yale Manufacturing Company, Limited, have been added to the colony, while the Getty & Scott Company, Limited, spread out into two annexes, now having Factories No. 2 and 3.

Among the new firms is that of McCaskey Systems, Limited, in a new building bought by them before removing from Toronto to Galt. In transportation field the outlook is good. At the present time the C. P. R. is engaged in spending its appropriation of $1,000,000 in the city. A new spur line is being built to the heart of the city, the project involving the erection of a downtown station for the Grand River Railway and the Lake Erie & Northern, the company's electric feeders, stretching from Waterloo and Kitchener to Brantford and Port Dover.

GUELPH HAS EIGHT NEW ONES

And Several of the Plants That Are in Operation There are Going to Extend Their Premises in 1921

By K. WESTABY, Secretary Guelph Chamber of Commerce

GUELPH, ONT.—The City of Guelph has made steady progress during 1920. Eight new industries have established themselves in the city, and are as follows:—

Moncrief Furnace & Mfg. Co., the Canadian branch of the Henry Miller Foundry Co., of Cleveland, Ohio.

The Erin Casket Works.

The Guelph Brass Works.

The Federal Electric Washing Machine Co., being the Canadian branch of the Chicago firm.

The Regent Textile Co., from Montreal.

The Sherer-Gillett Co., from Chicago.

The Shinn Mfg. Co., from Niles, Michigan.

The National Standard Co., from Niles, Michigan.

The Moncrief Furnace & Mfg. Co. are to erect a modern foundry building on their property acquired on the York Road. The Erin Casket Works, the Regent Textile Co., the Federal Electric Washing Machine Co. and the Sherer-Gillett Co. have all purchased existing factory buildings, which in nearly every case they have enlarged and improved.

The industries of the city at the present time number 129, and among the improvements made are:—

An addition, three storeys in height, 53 ft. x 90 ft., to the Shinn Mfg. Co.

The Canada Ingot Iron & Culvert Co. are building an entirely new factory building between George and Clarence streets. The plan calls for two buildings, 48 ft. x 290 ft. and 120 ft. x 132 ft.

The International Malleable Iron Co. have completed and are now occupying an addition to their plant of 240 ft. x 260 ft., two storeys in height, and in addition to this they have just acquired 12½ acres additional property, on which to erect a drop forge foundry building and other additions.

The Gilson Mfg. Co. have just completed an addition to their premises 80 ft. long by 120 ft. wide, three storeys in height.

The Louden Machinery Co. are now occupying an addition to their foundry 50 ft. x 106 ft.

The Northern Rubber Co. completed their new building this year. The building is 80 ft. x 200 ft., 4 storeys in height, and is said to be one of the most complete factory buildings in Ontario.

The Partridge Rubber Co. are occupying an addition just completed 150 ft. x 120 ft. wide, four storeys in height.

In addition to the above the Taylor-Forbes Co. are planning to erect a new factory building that, it is said, will cost $280,000. The Guelph Carpet & Spinning Mills have announced their intention to erect an entirely new building in 1921. The Sherer-Gillett Co., of Chicago, have purchased ground on North St. and have announced their intention to erect an additional building on this property next year.

The population of the city has shown an increase for 1920 of 980 people, and the assessment has increased during the year by $1,162,000. In this is included new houses that are valued at $410,498, which are now in various stages of completion. The prospects for the city for 1921 are very bright and apparently there is no let-up as far as can be seen in any of the local factories, all of which are running on full time with plenty of work available for everybody.

OWEN SOUND HAS NEW PLANTS

Several Now Operating and Another Expects To be Turning Out Electric Washers Early in the Coming Year

By GEO. MENZIES, Secretary Owen Sound Board of Trade

OWEN SOUND.—Owen Sound is growing. During the past year several new industries have located here, viz.:

The Clinton Knitting Co.

The Circle Bar Knitting Co.

The Grey Mattress Co. and

Taylor Bros. Jam Factory.

The Clinton Knitting Company have already found their premises too small and are enlarging their factory to double capacity.

The Circle Bar Knitting Co. occupy a large three story building and are contemplating building an addition.

Another new industry is just about ready to commence manufacturing, viz.: The Slade Manufacturing Co., manufacturers of electric washing machines. This firm is now installing machinery and expect to commence operation about the 1st of January, 1921.

WIRE PLANT IS REBUILDING

Collingwood Industry is Being Reorganized And Expects to be Operating in The Near Future

By W. A. COPELAND, Secretary Collingwood Chamber of Commerce

COLLINGWOOD.—The largest development of importance in the industrial life of Collingwood during the present year is the fact that the plant of the Imperial Steel and Wire Company, Limited, destroyed by fire two years ago, is being rebuilt and is rapidly approaching completion, and expects to be again in active operation early in the coming year.

BELLEVILLE HAS SEVEN IN ALL

Claim to Have a Very Good Labor Market And Populous Surrounding Country—Prospects of More Factories Coming

By J. BONE, President Belleville Chamber of Commerce

BELLEVILLE.—During the past year seven new industries have located in Belleville, one of them being a branch of an American industry, namely, the Teco Company, makers of pancake flour.

Other industries are: H. A. Wood Manufacturing Co., Limited, makers of automobile valves; Toronto Hat Co.,

Limited, hats and caps; Natural Tread Shoe Co., Limited; A. S. Richardson Co., Ltd., manufacturers of wax figures and shop fixtures.

The Elliott Woodworking Machinery Co., Limited, along with the four last named industries, moved here from Toronto where they found much improved conditions in labor and power. Another new industry is the Judge-Jones Milling Co., Limited, who have built an elevator with storage capacity of about 40,000 bushels.

There is also the prospect of our securing a new glass industry and some others, all of them being attracted by the very desirable labor conditions and the populous surrounding country from which this city draws labor by motor bus, etc.

MORE U. S. PLANTS ARE COMING

Hamilton in Negotiation With a Long List, Some of Which Will Come as Soon as More Power is Available

By C. W. KIRKPATRICK, Commissioner of Industries and Publicity, Hamilton

HAMILTON—Despite the handicap of electric power shortage, from which practically all of the Ontario municipalities have been suffering for the past two or three years, Hamilton during 1919 enjoyed another period of unusual industrial development and prosperity. Lack of a sufficient power supply unquestionably kept a number of large manufacturers, particularly Americans, from locating, but inasmuch as the conditions existing in Hamilton were typical of power conditions existing in other desirable Canadian manufacturing centres, the majority of the industries did not decide to locate elsewhere, but wisely deferred action until such time as conditions right themselves and the situation becomes normal. Present indications are that with the coming of spring, or about April 1st, power problems, at least so far as industries are concerned, will become a thing of the past, and as a result increased industrial activity may be looked for during 1921. A number of American manufacturers, with whom the local industrial department had negotiations during 1920, intimated their intention and desire to resume these negotiations just as soon as the Hydro Department was in a position to discuss all-the-year-around power contracts and there are, therefore, good reasons for expecting that 1921 will be a banner one in industrial activity.

But, to get back to 1920, Hamilton has no reason to complain of its industrial growth during this year of more or less abnormal conditions. In fact, with the exception of 1919, it was probably the best year the city has enjoyed industrially since 1911. A total of 25 new industries was added to the city's already long list, and while the majority of them were comparatively small, being capitalized at from $25,000 to $100,000, many of them are branches of large American concerns that give promise of speedy development, providing that tariff and other conditions continue favorable to Canadian industrial growth. Among the branches of American concerns to select Hamilton as their Canadian headquarters were:

Peterson Core Oil Co., Chicago, Ill.
Canadian Nathan Co., New York, N.Y.
Don-O-Lac Co., Rochester, N.Y.
Metlskin Co., Rochester, N. Y.
Moto-Meter Co., Long Island City, N.J.
Canadian Libbey-Owens Sheet Glass Co., Charleston, W. Va.

American capital is largely interested in others of the new industries, although they are not actually Canadian branches of existing American companies.

The largest new industry to locate in Hamilton during the year was the Canadian Libbey-Owens Company, manufacturers of sheet glass under the Libbey-Owens patent. The Canadian company is capitalized at $5,100,000, and its Hamilton plant, which is now under construction, will, when completed, represent an expenditure of upwards of $2,000,000. Although building operations are being rushed, the contractors estimate that it will take nearly a year to complete the buildings, but when completed they will be the last word in glass factory engineering and construction.

The city's industrial building permits for the year total considerably over $2,000,000 and this figure does not represent more than one-half the actual value of the buildings erected.

In addition to the new industries secured, there was, during the year, marked development among the existing industries. The Dominion Foundries and Steel Company recently completed the erection of new buildings and installation of one of the finest plate mills on the continent, at a cost of a million and a half dollars; the Canadian Cottons, Ltd., has, nearing completion, a seven story spinning mill, which represents an outlay of close to a million dollars; the Steel Company of Canada has under construction a wire products mill, which represents an expenditure of about half a million dollars, while the Mercury Mills, Chipman-Holton Company and other textile industries made very considerable extensions during the past twelve months. The progress of the city can best be gauged by the assessment returns completed in October 1st, last, which show an increase for the year in the assessment of upwards of $30,000,000 and in the population of 6,623.

Hamilton's industrial growth is the more remarkable in view of the fact that the city does not offer any special concessions in the way of bonuses, tax exemptions, fixed assessments or land grants to incoming industries. It has found from experience that the really desirable industries do not seek special favors but are willing, when manufacturing and distributing conditions are favorable, to become part of the community on equitable terms, bearing their fair share of the tax and other burdens and enjoying to the full the privileges the municipality offers. One or two industries were lost to the city during the year by reason of the evasion of Anti-Bonusing Act by some of the smaller municipalities, but, on the whole, Hamilton has no reason to regret its stand against the purchasing of new industries at the expense of the smaller taxpayer. That its policy meets with the approval of the manufacturers themselves is shown by the fact that the biggest boosters for Hamilton in the securing of new industries are manufacturers already located here.

SHERBROOKE HAS HAD MANY

Many Industries Went There in 1920, and Conditions Are Reported as Being Very Favorable There Now

By J. H. BROSSEAU, Secretary-Treasurer Sherbrooke Board of Trade

SHERBROOKE, QUE.—The following manufacturing companies with details in regard to their production and number of employees may be of interest to your publication:—

Julius Kayser & Co., Ltd., manufacturers of high-grade silk gloves, hosiery and underwear; number of employees 500; cost of plant $1,000,000.

The Superheater Co., Ltd., manufacturers of superheaters for locomotives and marine and stationary boilers; number of employees 150; cost of plant $200,000.

Canadian Sturdy Chain Co., Ltd., manufacturers of shirts, collars and cuffs; number of employees 150; cost of plant $50,000.

Regal Tire & Rubber Co., Ltd., manufacturers of automobile tires; number of employees 100; cost of plant $300,000.

Cluett, Peabody & Co., subsidiary, manufacturers of shirts, collars and cuffs; number of employees 150; cost of plant $50,000.

The Canadian Connecticut Cotton Mills, manufacturers of tire cotton fabric; number of employees 1,000; cost of

extension when completed will represent an investment close to $5,000,000.

Pressure Proof Rings Co., Ltd., manufacturers of pressure proof rings; number of employees 25; cost of plant $25,000.

English & Scotch Woollen Co., manufacturers of men's clothing; number of employees 100; cost of plant $25,000.

Also Office Requirements, Limited, Goupil, Limited, J. H. Bryant, Limited.

One or two of our industries are feeling the effect of the depression to a certain extent, but the great majority have orders on hand which will tide them over to the revival of business. As a whole, will say that the industrial situation in Sherbrooke is in a prosperous condition.

A technical school will be built at the cost of several hundred thousand dollars. Municipal Hydro-Electric power development at Two Miles Falls, at an expenditure of over $500,000, will provide 5,000 additional horse-power for new industries. Sherbrooke has over 60 industries and its manufacturing products total over $50,000,000 per year. There are ample housing facilities to accommodate all the labor required to work all the plants now standing. In addition the city is now spending over $600,000 on a model city suburb of workingmen's dwellings and the program calls for 200 houses of modern design. The labor situation was never better, all kinds of labor is available, including male and female, both skilled and semi-skilled; the working man is happy and contented in this section of the country, no foreigners or Bolshevists in this locality. Our labor population understands that capital is absolutely necessary and capital knows that labor is equally needed, consequently with this reasoning, strikes are foreign to our people.

MORE WAREHOUSES ERECTED

Regina Grows as a Distributing Centre—More Building in View For the Coming Year —Many Homes Going Up

By CHAS. A. COOKE, Secretary-Manager Regina Board of Trade

REGINA—Despite adverse conditions created by the enhanced cost of material and labor, the City of Regina has experienced a large amount of industrial progress. Commodious warehouses have been erected by Wood-Vallance Company, Fairbanks-Morse Company, Goodyear Tire Company and the Saskatchewan Co-operative Creameries. The Leader Publishing Company have also added to their holdings a large storehouse.

Other constructions during the year embrace the new Presbyterian Carmichael Church built at a cost of $40,000; power house at the Parliament Buildings; four-storey business block of the Regina Trading Company; new Capitol Theatre, and upwards of 200 residences.

Projects for next year include a distributing house for Canadian Swift Company and a college to be erected by the Lutheran body.

SASKATOON'S RAILROAD SHOPS

Building Figures of the Year Show Very Marked Increases Over Previous Year— Big Car Shops are Contemplated

By GERALD GRAHAM, Commissioner Saskatoon Board of Trade

SASKATOON—The outstanding features of the 1920 building program in Saskatoon have been the beginning of construction of new C.N.R. shops and round house, the new Provincial Normal School and the new Physics building of the University of Saskatchewan. As part of the C.N. Railway program a new bridge is also to be erected on the side of the existing one. With the establishment of the mid-Western headquarters at Saskatoon it may reasonably be expected that further building will take place this year, also solve the completion of extensive new freight office and general superintendent headquarters and extensions of the express companies premises now under way. The sum of $800,000 has been set aside for immediate work here, but confirmation of the figure is not obtainable. The new Normal School is well under way and the site, overlooking the whole city, is exceptionally advantageous. The building is to be in brick and Bedford stone in the Gothic style, similar to that which the University of Saskatchewan has in all its buildings. The building will cost approximately $750,000. The Physics building at the university will, of course, conform to the style of others on the campus and the building permit shows a minimum expenditure of $403,000. Some of the other larger permits during the latter part of last year and during the past summer are as follows:—

Description of Building	Minimum
Coca-Cola Company	20,000.00
Franklin Garage	12,000.00
Chevrolet Garage	15,000.00
Y.M.C.A. Hut	20,000.00
Roy Garage	15,000.00
Auto Garage	20,000.00
Barries' Limited store	20,000.00
Addition to C.P.R. station	20,000.00
Riddell Carriage & Motor Works	20,000.00
Green Court apartment house	20,000.00
Imperial Bank alterations	15,000.00
Drycleaning establishment	20,000.00
Quaker Oats Co., Ltd., additions	86,000.00
Physics building at university	403,000.00
Mayfair school	184,000.00
C.N.R. roundhouse	45,000.00
New skating rink	25,000.00

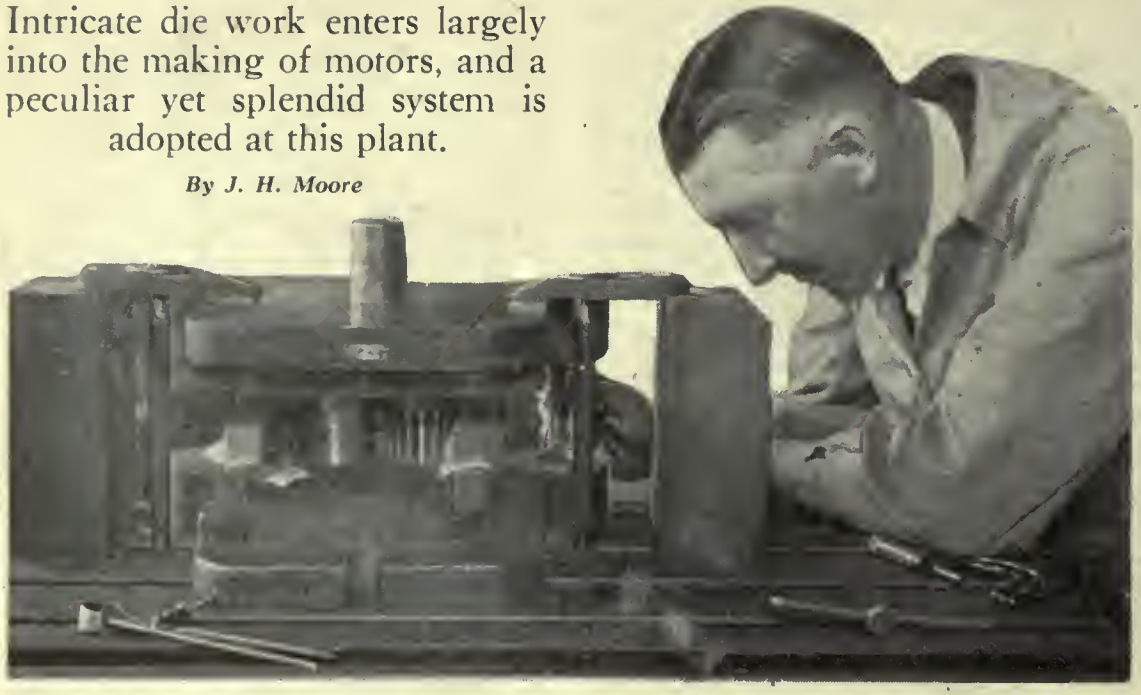
For the year ending September 29th, 1919, the total of building permits was $1,359,390 and for the year ending September 20th, 1920, the total is $5,160,105, thus indicating that a considerable building program of a public character has been under way. One of our most pressing needs is a larger hospital which has been considered for some years and which will be undertaken as soon as the city has funds. The matter of a public library is in the same category.

SUCCESS is not made by lying awake at night, but by keeping awake in the daytime

Turning Out Small Motors in Quantity

Intricate die work enters largely into the making of motors, and a peculiar yet splendid system is adopted at this plant.

By J. H. Moore



SPLENDID working conditions, ideal lighting, novel and accurate die work, these are some of the features found at the Canadian plant of the Robbins and Myers Co., Ltd., Brantford, Ontario. The data to follow will not only cover a brief description of the plant itself, but will include details of operations performed, items of general interest, and a detailed account of how this concern prepare their product.

Before entering the plant, one is struck with its neat exterior appearance. The building is of one story construction. The main office occupies the centre portion of the building at front, while the women enter at a right hand entrance, the men at a similar left hand door.

Beautiful flower beds, and a lawn of deep green give the building a regular country aspect, but on entering the plant one is really not sure whether he is actually inside a building or not. The lighting is perfect. A good high roof, well windowed and ventilated, throws ample light down, while the sides and end of the factory are also well provided with similar windows. Any plant arranged in the manner of the one we are speaking of, certainly deserves favorable comment.

The flooring is of wood blocks tarred in, and, as is well known, this type of floor saves to a considerable extent the workers' feet, the placing of machinery has also received close attention, the various departments being well laid out, and the machine tools segregated to the best advantage. Ample aisle space is allowed, in this way avoiding any confusion or congestion of trucking. Quite a number of operations performed at this plant are accomplished in a sitting position, for which splendid benches and stools are installed. Even the tool room operators are blessed with stools to sit on while their work is being completed. Tool stands are placed alongside each machine tool, and while the initial expense may be greater, the benefits derived soon pay for these stands.

Production Aids

For transporting material in the different stages of completion throughout the plant, trucks, and special stands are used wherever possible. It pays to make these, as it speeds up the work and keeps it so separated that it is easier handled.

Air lines are placed handy to all machine tools, and are used extensively to clean the tools of dirt, cuttings, etc. There is no need to go into detail regarding their raw stock and cutting off department, except to say that it is modern in every respect, and well arranged. As this is not intended to be a mere descriptive article, let us leave the generalities, and tackle the various departments one by one.

The Press Department

This section of the plant is set out by itself and the presses are arranged in a long line. Brown and Bogg presses are used, also presses made by the Bliss Co. The work performed is piercing, blanking, forming, and drawing, but as we intend showing these dies further on in the present article we need not dwell on this point at the present time.

Automatic Screw Department

This section is very well equipped and includes some large and small motor driven Cleveland and National automatics. There are also some No. 4 Warner and Swasey small lathes. The machines are arranged in ideal form. Screw work of all kinds is done in this department, also the turning of short shafts, pins, etc., etc.

Machine Department

In this section they have a full complement of floor grinders, buffers, disc grinders, Jones & Lamson lathes, Natco, and Leland Gifford drills. To give readers some idea of the work going through this department we have taken the operations performed on the washing machine motor body and head. This is of course only one type of motor, but will give readers an idea of the work entailed.

The Jones & Lamsons used are mostly of the double head type, and following are the sequence of the operations. The castings first go to the grinding end of the department and rough portions taken off. Now comes the turning of the head, which entails two operations, the turning of the inside, and outside fit.

The bodies are next bored out and faced. The photograph shown at Fig. 1 illustrates this operation, and it might be well to state that the hole is approximately 6⅜" diameter, and is finished 3¼" deep. The first station faces off the work by means of two ordinary tools, the second position has roughing mill cutters, and a roughing reamer for the centre hole, while the third position carries a boring tool for the centre hole. The last station holds the finishing mill cutters, also the finishing reamer, which is of the ball floating type.

Drill press operations on both the heads and bodies come next in order, but there is hardly any need to enter this in detail. Sufficient to say there are eleven operations.

After these operations have been performed, the parts go to the paint department, where they are sprayed with two coats of enamel. They are next placed in a Hoskins electric oven, which holds two racks, or approximately 600 to 700 parts at a time. They are baked in this oven for about three hours.

The operations on the Hoover suction sweeper motor while not exactly similar, entail the use of like equipment, so that we will pass on the winding department, together with the line of all machines used in conjunction with this department. These machines include Heald, Norton, and Landis grinders, Porter cable motor and belt driven lathes, some small Dalton bench lathes, some Mulliner lathes, some Rockford small lathes, a high speed riveter made by the High Speed Hammer Co., some Leland Gifford drill presses, and other tools of like nature.

FIG. 1—BORING AND FACING THE BODIES OF WASHING MACHINE MOTORS.

Winding Department

The work entailed in the making of a motor for a suction sweeper is more than one would imagine, and while we cannot, in this space, tackle all parts and operations in detail, we give a few to illustrate the varied work. Take for example the shaft shown at H, see Fig. 2. This part goes through the following operations. First, the two shoulders are nicked by means of a special double tool on the lathe, then the second and third steps are turned to size. The wick hole is now drilled, and this operation is worthy of special mention. The hole is 3/16" diameter, and is drilled through the centre of the shaft until a depth of 4" is reached. The drilling of such a small hole to a depth of 4" is a rather ticklish proposition, but they have overcome the difficulty very nicely.

A circular tank has been placed on the drill press table containing a good supply of soap water. In the middle of this tank, and in a vertical position, is the drill. It is held stationary of course. The work to be drilled is held in a quick grip chuck in the drill spindle, and revolves at a good rate of speed. The operator feeds down his spindle, relieving the work as often as deemed advisable. The method as described has resulted in greater production with less breakage of drills, insomuch that the work being drilled in a tank of soap water cannot clog, thus saving both time and drills.

The next operations in sequence are as follows: An oil hole is drilled, the slots for the two keys shown are milled, the first, second, third and fourth steps are ground, then the discs are assembled

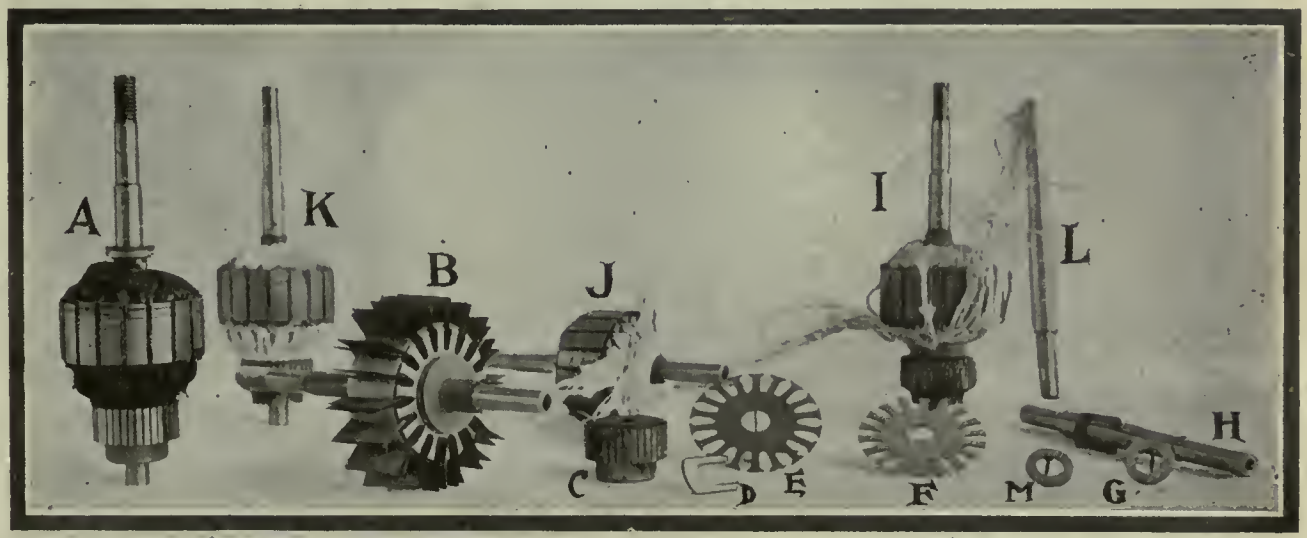


FIG. 2—THE VARIOUS STEPS ARE SHOWN IN THIS PHOTOGRAPH. FOLLOW THE TEXT TO GET THE BENEFIT OF THIS LAYOUT.

FIG. 3—WINDING AN ARMATURE.

on the shaft. Following this, the discs are straightened in the core, then sent to the winding department. Fig. 3 illustrates one of these winding machines at work.

In order that readers may get the greatest benefit from the description of these various operations we have photographed at Fig. 2 the shaft, and the parts going to make up a completed armature. We have lettered these parts so that the description can be easily followed. For example, A shows the complete armature, B illustrates one of the sections, while C shows a commutator complete, D depicts one of the wedge shaft keys, E the metal sheet disc, and F the fibre disc. G shows a fibre washer, H a completed shaft with a key partially inserted. I depicts the armature ready for inserting the leads, J the armature ready for the commutator, K the armature ready for soldering the commutator, L represents the shaft in the rough, while M depicts the steel thrust washer.

The view opens one's eyes to the number of parts entering into the makeup of a complete armature, and the photograph of course shows but one type of armature made at this plant.

Assembling

We will now suppose we are going to assemble an armature as shown completed at A Fig. 2. The shaft is first banded with gummed paper, then the slots are insulated with fibre sheets forced into a sort of a U shape as shown. Previous to this, of course, one of the keys has been driven into position and the discs placed on the shaft. First comes a fibre disc next to the key, then come the metal discs, finishing up with another fibre disc, and the second key.

After the insulation has been placed in the slots, the armature is wound as shown in detail view at Fig. 3. These machines have dials on them somewhat similar to a milling machine disc plate. A series of holes go around the outside, and there is a brass pointer which can be set at any position. The holes are numbered from one, up. Depending upon the armature to be wound, the wheel or dial must turn so many holes past the pointer, which, by the

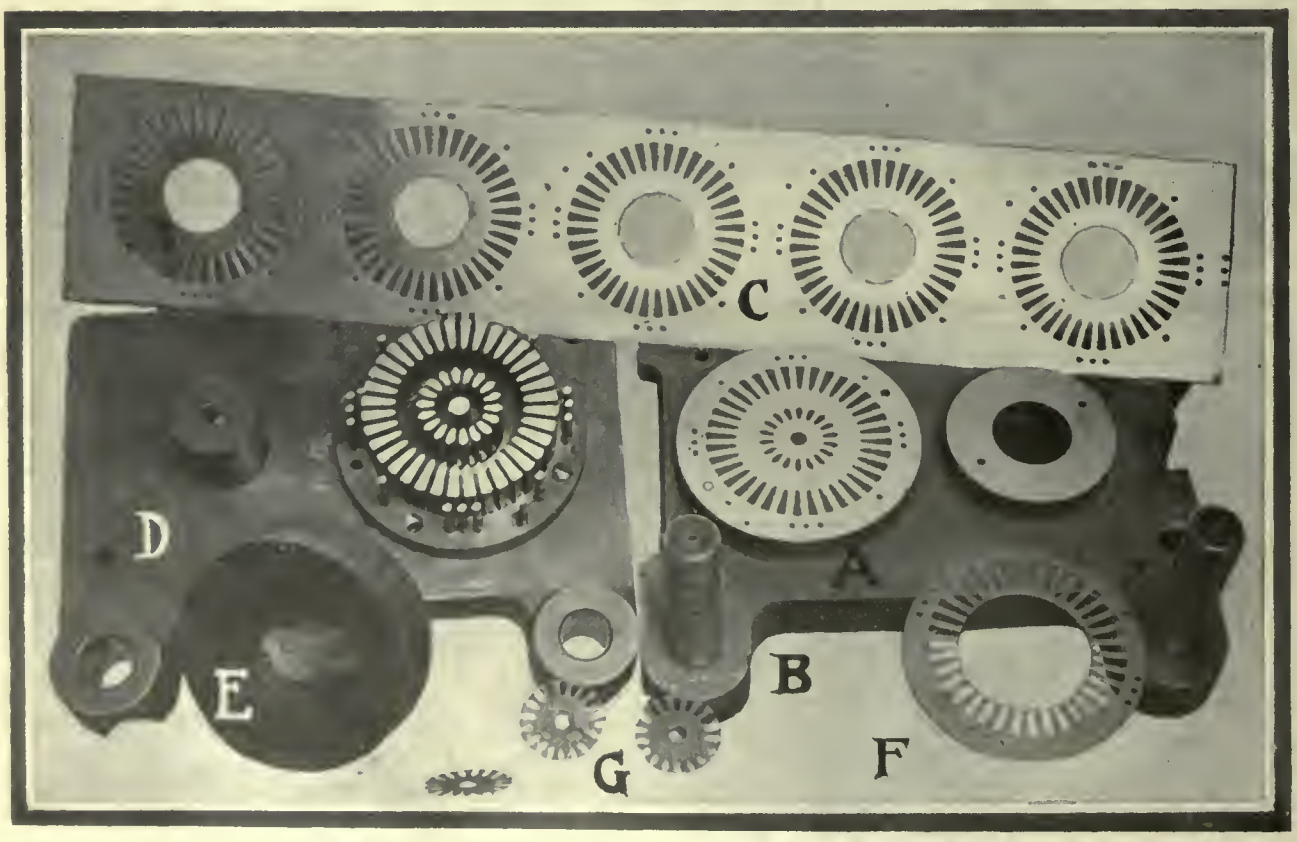

FIG. 5 HERE IS A GOOD EXAMPLE OF A DOUBLE ARMATURE DISC DIE.

FIG. 4—SOME OTHER DETAILS OF INTEREST, DEALING WITH MISCELLANEOUS PARTS.

way, never moves. To watch the girls judge the correct number of turns, which may run into so many revolutions, plus so many holes is a treat. Like everything else, they get so used to it that the action becomes second nature.

After winding, the fibres are bent down, then the work is tested for opens

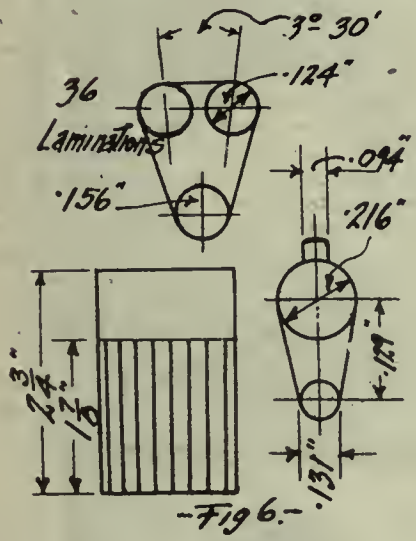

FIG. 6—DETAILS OF SLOTS, AND DEPTH OF PUNCH MILLING.

and grounds, after which it is thoroughly inspected.

The commutator is next pressed on, and the leads inserted. The soldering of the leads comes next. Inspection of the soldering follows, also greasing of the shaft. The commutator is now rough turned, and the shell turned to size to suit a little protection cap that goes over it. It is now tested for grounds, opens, reverses and shorts.

After these operations, the work is dipped in insulating varnish, and put in an electric oven, where it is baked for 10 hours. The thrust washers are next pressed on, and the shaft straightened, as it is imperative that the shaft run absolutely true. The first washer is now faced, and the distance over all between the face of this thrust collar, and commutator shell is procured. The commutator is next finish turned and sanded with No. 00 sandpaper.

The core is now ground, and the front end of shaft is finish turned to size. An oil hole is next drilled in the commutator shell, and is so drilled, that a continuous stream of oil reaches both the top and bottom bearings. The work is now balanced, and the balance is made up by means of small wedge-shaped pieces of brass. The fibre washer is next pressed on the shaft, after which it is faced. A small slot is milled at the end of the shaft, when the now completed armature is sent to the test department. Considerable information of value can be gleaned by following these steps of manufacture with the photograph showing group at Fig. 2.

Field Core and Other Parts

To follow the next operations, let us refer to group shown at Fig. 4. A, represents a field core, and of course these are first punched out in the press department. On reaching the assembling

FIG. 7—ILLUSTRATING THE METHOD OF FINISH FORMING SLOTS IN ARMATURE DIE.

FIG. 8—SHOWING TWO OF THE FILING MACHINES AT WORK.

stage they are put together in the following manner. An assembling fixture is used which gauges the correct number of discs to make up the core. Two rivets hold the core together.

They are next ground, and as there is a flat spot on each side of these cores, they are placed on a mandrel, and are staggered so that the grinding wheel is always removing stock. The grinding of the outside diameter is the next operation in sequence. It might be well to mention that in the assembling of these cores this concern has employed a blind man as one of their assemblers, and in spite of his handicap he can turn out as good work as the others. To watch him perform is a sight in itself, and were one unaware of his affliction, they would hardly believe such to be the case, so dexterous are his movements.

The cores being ground, the coils are next given a slight curve in an air press. This coil is noted at B in the photograph. After being formed they are inserted in the core, and the terminals are next soldered to the coils.

Making the Commutator

The punchings, both copper and mica, are made in the press department, and on arriving at the assembling department are placed in circular form as follows: A copper section, a mica section, and so on. The sections are pressed into a steel ring as shown at C. The sleeve is now insulated, as shown at D, after which sleeve and collar are assembled. The commutator is next locked by means of a wire and pressed out of the ring. This is shown at E.

They are now inspected to see that copper and mica are perfect, after which they are covered with bakelite and baked. A rough cut is next taken off the outside diameter of commutator, then the rear shell is faced to length. The holes are next reamed to size, and one end of the hole is chamfered. The sleeve is now milled with a small slot at its end. They are next tested for shorts and grounds, after which they are ready to assemble on the armature.

Field Coils

The field coils are first wound to the specified number of turns, and taped with what is known as empire cloth. This cloth is really a sort of linen, so coated that it takes 2,000 volts to jump through it. This provides a perfect insulation. They are next taped with muslin tape, the leads are soldered, after which they are dipped in an air drying black varnish. On coming out of the dip they are allowed to dry in the air. There are, of course, other innumerable little details such as turning of brush rings, bearings and so on, but sufficient has been given to illustrate the systematic method of following up this class of work.

To make a washing machine motor is an entirely different proposition as the design is different in many respects, but we will not enter into this matter, as some of the work is very much a duplicate of that already described. The other parts shown in group at Fig. 4 are as follows: F illustrates a single disc of which the completed field core is made, and C shows the same in an assembled state with the coil attached. H and I illustrate the copper and mica sections going to make up the commutator shown at J. The other portions need not be lettered as they are merely parts going into the make-up of a motor. The brush rings can be clearly noted and need no special comment.

The Die Department

It is hardly necessary to call reader's attention to the fact that work of the nature we have just described entails considerable punch press work. This work is also of a very exacting character so that the data to follow on the die department will in itself be of real value to the mechanic. It is not often one runs into a similar line of die work and for that reason we have gone into the matter very carefully, giving figures of value and interest to the mechanic in general.

Die work at any time is a fascinating subject, but the dies about to be de-

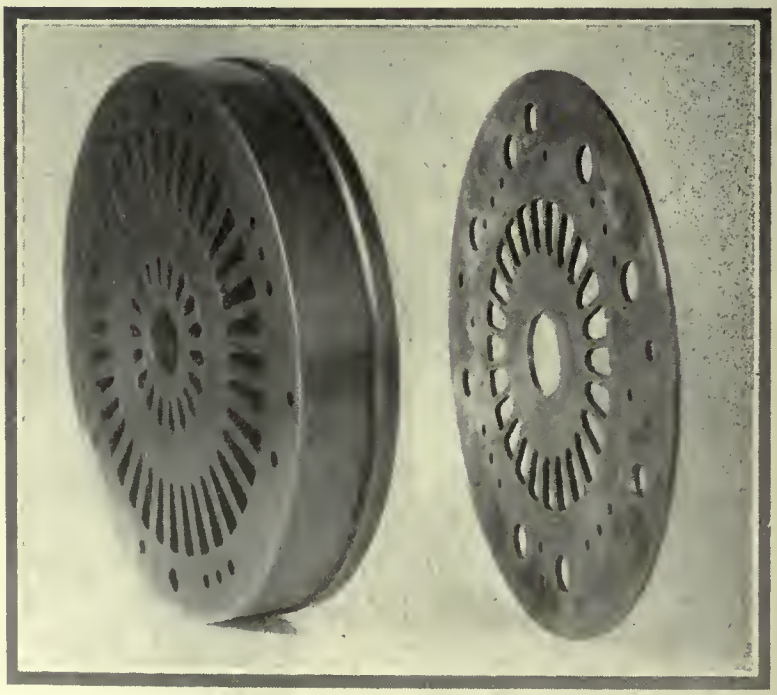

FIG. 9—A NEW AND USED DIE BLOCK. THE NEW ONE IS 1¼" THICK. THE USED BLOCK ONLY ⅛" THICK.

scribed are of more than passing interest. Their armature disk dies are the chief feature, but before speaking of the die, it might be well to explain that these disks are made from a grade of sheet iron approximately 0.025" thick, termed electric iron. This material is used because of its low resistance to an electric current, or to use the proper expression, the material is used because of its permeability. Though very soft, it is difficult to punch, the wear on the dies being considerable. In the average plant, a die of the nature shown at Fig. 5 would be made altogether different from the method employed by this concern. The photograph depicts a double armature disk die, the outside punching being for a larger motor than the inside one. To give readers some idea of the dimensions of the slots in blanking die A is made from a solid piece of steel in which the required number of slots are machined. The die fits into a slide in the die shoe B, and is held as shown. C illustrates a portion of stock punched, D the punch block itself, E some assembled disks of the large size, F as a single disk after centre portion has been blanked out, and G two of the centre disks. It will be noted that the first portion of the die punches out both the slots for large and small size disk, and to give readers some idea of the task let us refer to Fig. 6 together with the following description:

There are 36 slots in the outer die, these being .156" at the small end, and considerably wider at the other. Two .124" holes are drilled 3 degrees and 30 minutes apart, then slots are filed to a finish. The inside disk has 18 slo..

concern at the present time. Ketos steel is also used with considerable success.

The die block is first cleaned up all over to ensure getting below the decarbonized surface. They now heat the block to either a blue or a yellow color. This is done for marking off purposes, as they do not use the regular style of wiping the block with soapstone. They claim such an artificial surface wears off before the die is completed and is not suited for their purpose. Having colored the block, they proceed to mark off the die, but again deviate from all regular practice. No templets are used, the die being laid off direct from the drawing. This statement may not sound much to the layman, but to an experienced tool maker it speaks of much needed accuracy and confidence in one's laying out powers.

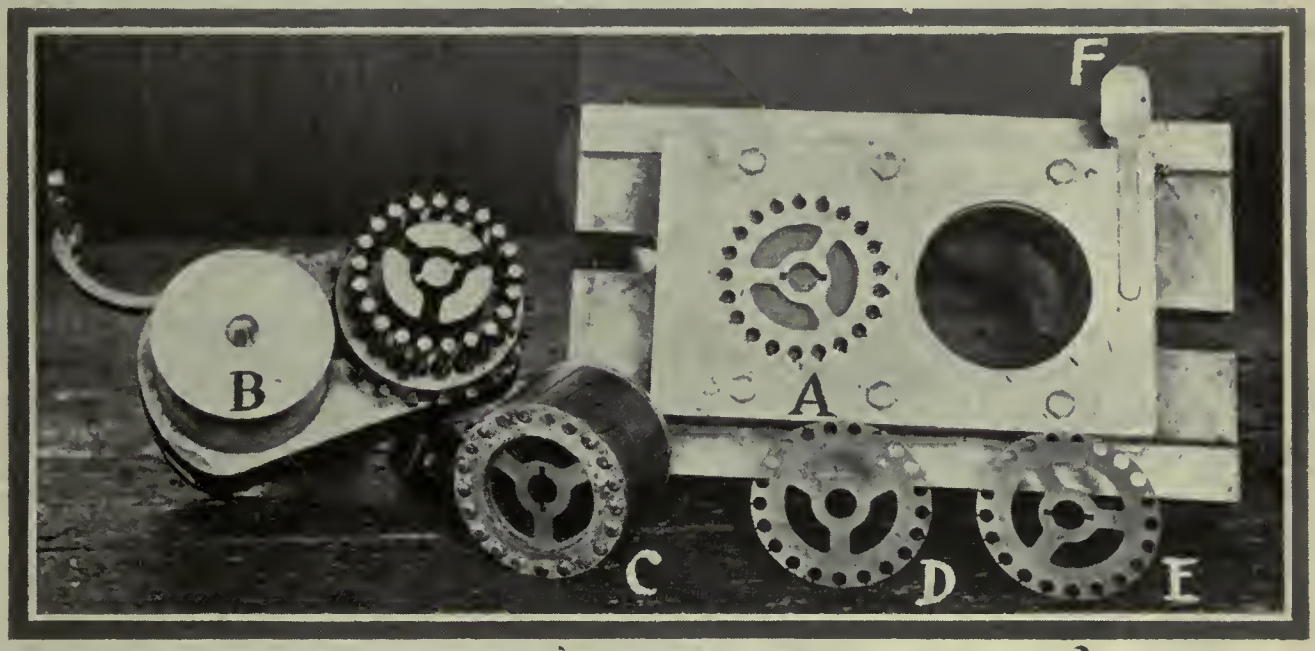

FIG. 11—ARMATURE DISK DIE FOR 17WW MOTOR.

these dies we have drawn the sketches shown at Fig. 6.

It has been considered bad practice by some concerns to make such dies or punches solid, because the thin strips of metal remaining are likely to warp in hardening and break. Another argument made is, that if made solid, repairing becomes more difficult.

These objections have been swept to one side as far as the firm we speak of are concerned, for not only do they make their dies solid, but their punches as well. This procedure not only calls for good tool work, but mighty particular care in the hardening operations.

Construction of Die

It would seem that all regular practice has been tossed aside in the preparing of these dies, for the die shown is not even of the sub-press type, as usually followed out, but is of the plain blanking type of construction. The the slot in this case having a tit as shown. This tit is .094" diameter. The large portion of slot is .216", the small part .131". The distance between the holes drilled is .129". These dimensions if studied will show the care that is necessary in completing such a die correctly. The punch is another ticklish proposition; as can be noted the slots go down 1⅞" deep, and of course the punch must suit the die.

Let us suppose we are watching the making of a die similar to that shown in the photograph. The die shoe is first machined to size on the shaper, and as this is ordinary tool work, we need not dwell on the matter. The shoe being completed it is passed over to the man making the die.

The steel used in the making of the die block is always of a guaranteed oil hardening, non-shrinkable brand, and it might be well to state that Vasco and Deward steels are being used by this

The block is now ready for working out the elongated slots which form the projections on the armature disks, and the first step is to drill a series of equidistantly spaced holes entirely through the block. This work is done on the milling machine, the dividing head being used for spacing of holes exact. A Bushing type of drill chuck is used in the miller spindle, and this chuck carries a drill of the correct diameter. The internal ring of holes is usually drilled first, then the size of drill is changed when the exterior holes are next drilled. Sometimes the procedure is reversed. Following this, a series of holes are drilled so that they just break into each other. After these holes have been completed the intervening webs are removed by shifting on the large disk shown at Fig. 5. 296 holes were drilled before the webs would be drifted out.

The next step is to finish form the slots, this being performed as shown

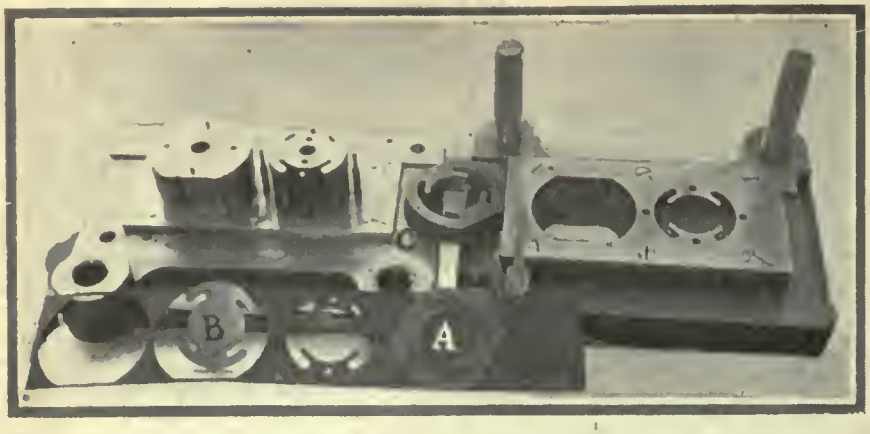

FIG. 12—DETAIL OF A FIELD CORE DIE.

at Fig. 7. The work is done on a No. 2A Brown & Sharpe miller with a slotting attachment placed on the spindle head. The die is mounted on a tapered arbor, which is held in the dividing head of the miller, while slotting tools of the correct shape are fastened into the head of slotting attachment. The dividing head is held perpendicular, and the slotting attachment is also set perfectly square, this producing a straight hole. The clearance is produced in the filing operation which will be described later.

The sides of the slots are machined first, after which the two arcs are completed. The outer arc has a slot as already described cut into it, and for this operation a tool of suitable shape is used to cut the slot. As before, the indexing attachment of the dividing head is used for spacing of the holes. Very light cuts are taken during their operation, as were one to attempt a cut of even 1-64", distortion and general springing of the tool would result. Patience is a virtue on this work, care, rather than speed, being the chief consideration.

Finishing Operations

When these slots have been machined to their approximate size, the final operation consists of filing them to exact size on small filing machines as shown at Fig. 8. These machines are made by the Oliver Instrument Co., and consist of a table that can be set to any desired angle, and a file comes up the centre of the table of such a nature as to conform to shape of slot desired. The machine is driven by an individual motor. which by the way is one of their own make, and in addition to filing the slots to their correct shape, the machine also produces the correct clearance angle.

Here is another point where this concern follows a peculiar trail. They only allow .003 inch a side on these dies, the block being 1⅛" thick. This means that the table of filing machine is tilted over approximately 7½ minutes. Imagine a die 1 1/8" thick with only .003 clearance aside, and still this allowance has proved a decided success, and allows them to grind their dies down to actually one-eighth of an inch thick. Sounds like a rather wild statement, but look at the photograph Fig. 9 of a thick and thin die, and be convinced. The die illustrated was made from Ketos steel.

The die block is now hardened, being heated up to 1375F. to 1650F., depending upon the nature of the steel and the shape and size of die. It is now drawn all the way from 300F. to 500F. For hardening, a Hoskins electric furnace, made by Hiram Walker & Sons, Metal Products, Ltd., Walkerville, is used. This is known as a high speed tool furnace and can be heated up to 2500F. if necessary. The heating is done gradually and uniformly until about 1100 F. has been reached before the hardening point heat is raised. The block is dipped into linseed oil and left to cool, after which the temper is drawn very slowly to relieve the strain.

The hardening of such a die as shown calls for considerable care, as the slightest amount of shrinkage or warpage would render it unfit for use. Being of the solid type it would be practically impossible to correct any distortion in hardening. It takes from five weeks to two months to make a complete die as shown, so that the loss would be considerable. It might be said, however, that although following out such a practice this concern have never yet lost a die in the hardening operation.

Making the Punch

The die block being now completed, let us consider how the punch is made. In all cases this concern make their dies first, then fit their punches to the hardened completed block.

The punch is made from a solid, round bar of stock, drilled, turned and recessed in the lathe. It is next slotted in the miller. The punch is driven on a tapered arbor, which is held in the dividing head of the milling machine, and a slotting saw of the required thickness is used to form the individual members of the punch. Depending on the size of the punch, two to five cuts are taken. The position of the cutter is always changed on the last cut. On some types of armature punches, where the slots between the different punch members vary in width at the inner and outer extremities, slotting saws of different thicknesses are used in order to reduce the amount of machining. When this is necessary, the saw is not inserted as already stated, but is raised slightly and the second saw is also raised. The remaining web is machined out with the slotting attachment.

In the case of a large punch, where five cuts are taken, the semi-circular, and the tit form are milled after the third or fourth cut. The change of cutters is made with a definite idea in mind, namely to use the form cutters before the members are split right through. This avoids chatter and distortion. The reason five cuts are necessary is self-apparent, namely, the punch must not

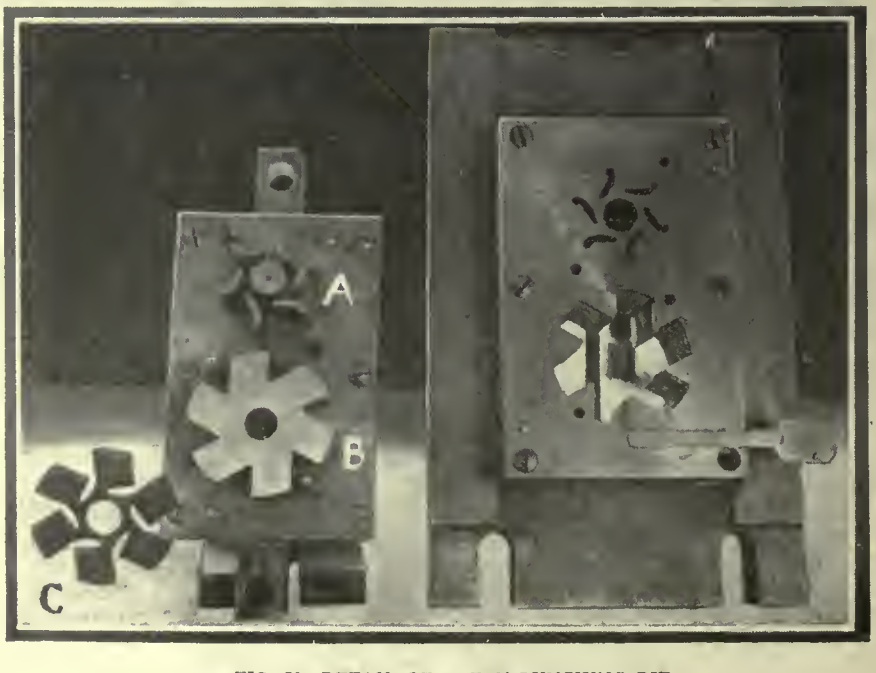

FIG. 13—DETAIL OF A FAN PUNCHING DIE.

be sprung in any way and a heavy cut would be sure to do this. The operations spoken of so far have been accomplished with the punch in a horizontal position, but in order to perform the finishing work, it must be turned vertically and the slotting attachment with proper shaped tools used. After this operation is completed a slight touch up with the file is all that is necessary.

The punch is now sheared into the die block for a distance of about 1/8" to ¼", when any excess stock is again removed. This shearing operation is performed on a regular style arbor press, and they are very careful to shear a very little stock at a time in order to place no undue strain on the finished die block.

The Guide Pins

As soon as the punch has been fitted correctly, it is assembled to the punch holder, and placed in the die for about 1 8 of an inch. The shoe with die in place, also the punch holder with punch in place is taken to the vertical miller, where the guide pin holes are drilled as shown in heading of this article. Note that parallel strips and paper keep the die and punch in perfect position while the holes for guide pin bushings are being bored. A Marvin & Casler offset chuck is used, which has a micrometer dial that makes it easy to set the boring tool to correct size of hole. This operation is known as the final drilling of guide pin holes, and after the work has been taken from the machine, the guide bushings are ground to fit the holes just bored. The bushings are next pressed in place, the guide pins assembled, when it will be found that the punch and die go together perfectly.

Believing it will be valuable data for tool makers in general, we append still further information on the die we have been speaking about. The clearance on the shoes to allow the punchings to drop out ranges from 1/64" to 1/32" a side, depending upon conditions, and every operation is set up on the machine by means of dial indicators. Every set up receives like care, for it is imperative that die be absolutely true. In order to secure an accurate measurement of the diameter of punches when milling the arcs, they use two round pieces of drill rod, letting them rest between two members of the punch. The micrometer measures the distance from these drill rods, then the distance equal to their diameter is deducted from the measurement found.

It will be noted by referring to the further pictures of various dies used, that one style of gauge is universally adopted. This is a very simple gauge and can be seen at F at Fig. 11. It consists of a steel finger, connected with a small spring to the stripper. On the punch block is a pin which hits the end of this finger as the ram descends, thus lifting the other end of the finger where gauge pin is inserted. This, of course, allows the stock to press through.

Before milling the punches, a small notch of about ⅛" wide, and of similar depth, is placed at the back of the punch. This notch keeps the punch from turning while being milled. They did this because they found that even though the punch was forced on a tapered mandrel, the vibration had a tendency to turn it. The adding of this small slot has overcome this difficulty.

As a rule the shoe is made about 2 11/16" deep, the die blocks 1⅛ to 1¼" deep, the stripper plate ⅜" to ⅝" deep and the guide pins from 1¼" to 1⅜" diameter. Wherever it is thought wise a pilot punch is used. For example, see the punch at Fig. 11.

The die Fig. 11 is used to punch the armature disk for their 17 W. W. motor, used on washing machines, and is certainly worthy of attention. As can be noted, there are 21 small punches used, each with a very small tit at the exterior. There is also the three web punch, and the centre punch, which has a tit on either side of it. As before, the die is made solid, and entails considerable accurate work. This portion is of course covered by the stripper A, but as it practically takes the same form, readers get the idea quite clearly.

The blanking punch B is made solid, and it will be noted that a small pilot is used to centre the blank correctly. The 21 punches already spoken of are made separately, but the three web punch is made from a solid piece. The centre punch is made separate, so that in reality, there are actually 23 punches used at this portion of the die. C represents an assembled core, D the disks used in the centre of the core, while E depicts the disk for which the die shown is made. Note that the only difference in these pieces is the absence of the tits in the disk D. F depicts the gauge, which has already been explained.

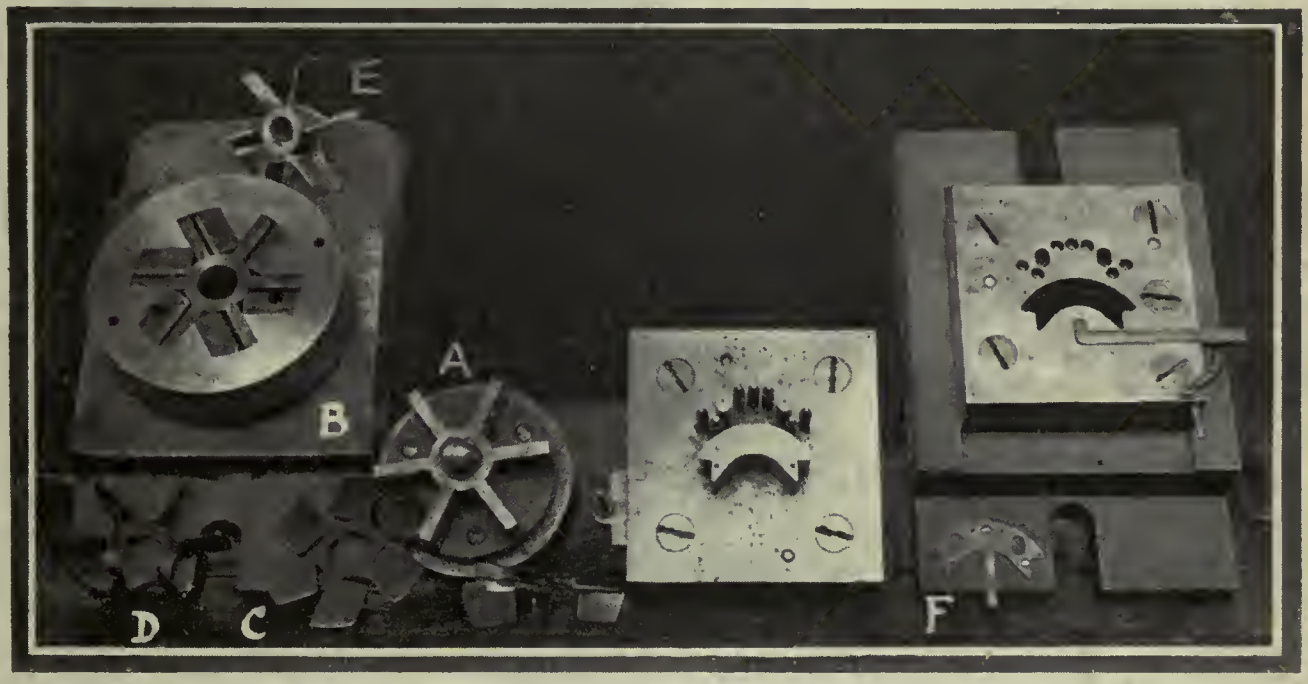

FIG. 14—ILLUSTRATING TWO DIFFERENT DIES. DETAILS ARE EXPLAINED IN THE TEXT.

Field Core Die

The die depicted at Fig. 12 needs little comment as it is self-explanatory.

Continued on Page 592

Making Parts for Universal Plate Mill

Operations in the making of universal rolling mill equipment—The machining of rolls, and boring work on sections—Machine work on certain parts of rubber mill equipment.

By J. H. Moore

NEW tendencies and developments in Canadian industry are always interesting. This is especially true of the variety of work at present proceeding in the plant of the Dominion Steel Products Company, Limited, Brantford, Ontario. To discuss all the classes of work being produced is not possible in this space, but we shall take up the two chief propositions which they are handling.

To explain the first proposition, we must in fancy travel to Hamilton, Ontario, there entering the plant of the Dominion Foundries and Steel, Ltd. Here we see this latter concern installing a huge Universal plate mill, and it was this very installation that created the demand for tables for the aforementioned mill.

To make tables for a plate mill sounds like an easy proposition, but is it? Ask the company at Brantford, and see what they say. The number of parts to tables of this nature is surprising, and to form some conception of the general appearance of one of these tables, let us refer to Figure 1. As will be noticed, the table consists of a series of rollers, driven by motors conveniently placed. Depending upon the length of the table, one, two, or four motors provide the driving power. Each roller has a bearing at both ends, and, as can be seen, a bevel gear is keyed to one end of each roller. This in turn meshes with another bevel gear on the power shaft. As a rule the power shaft is coupled up at various place, depending upon the nature and length of the tables. This of course means that all motors driving the power shaft must revolve at the same rate of speed, and to accomplish this the motors are arranged in synchronism. While we have shown the bevel gears in full view at Fig. 1, these are of course covered in actual operation.

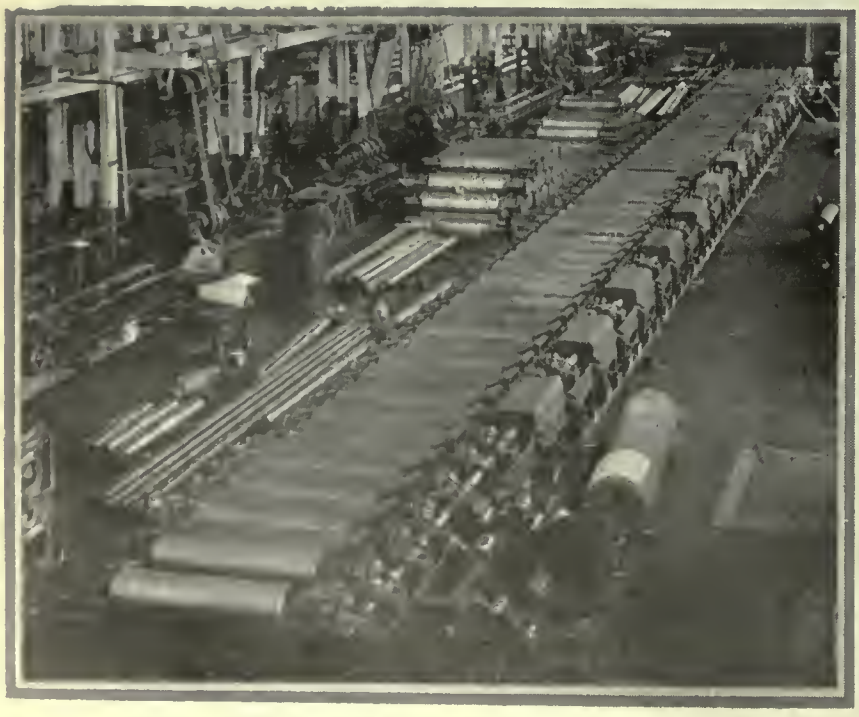

FIG. 1—GENERAL APPEARANCE OF ONE OF THE TABLES.

Without going into any details, let us run briefly over the various tables used, and the procedure in the making of a plate. The stock is of course taken from the yard by means of a crane, and placed in the furnace pusher. From this point the billets are pushed into the furnace, and on reaching required temperature come out on the discharge pusher. The stock next reaches the approach table, and, rolling up on this table, it soon reaches the front mill table.

It now passes through one mill, landing out in rolled shape on the back mill table. Continuing its journey, it passes from the back table to the runout table, and from there to a plate leveler. Next comes the hot bed, and in some cases more than one hot bed is used. The procedure from here on varies considerably, depending upon the nature of the plant, but sufficient to say there is still one more table, namely the back shear table.

We have quoted this routine of operations, not with any special plant in mind, but rather to bring before readers a general conception of the procedure.

The Sections

The construction of these tables is somewhat similar, being made up of various sections, bolted and keyed to-

gether. Take for example Fig. 2. Here we see six of the sections being machined on a Pond planer. The bottom of these sections is planed on four spots only, the rest being bedded in concrete when installed in place. The piece is then turned, and the top planed all over. Next the sides are planed as shown in the illustration, when other minor operations follow. As the photograph is self explanatory, we will pass on to a description of the main mill table section shown at Fig. 3.

This table section is 18 ft. 4½ in. long, 4 ft. 3 in. wide, and 2 ft. 1 in. deep. It has 13 roll bearings, each of 6⅛ in. bore. The first operation is performed on the planer. The bottom is planed on four spots, and the rest of bottom is bedded in concrete in actual use. Next, the work is turned, and the top planed all over. The side bearings are now machined to width and depth, there being five of these bearings, as shown at A. The work is next set up on a Landis boring mill, and the ends milled as shown at Fig. 4. This is a simple operation and needs no special comment.

The section is now set up as shown at Fig. 3 and the cap holes drilled. There are 44 of these holes to be drilled, the majority of them being 13-16 in. diameter, and they are drilled 10½ in. deep. The work is of course moved along as the job proceeds. The bearings are also finished at this boring mill and a peculiar practice is adopted in the boring of these bearings. The bottom half, that is the portion shown in sketch, is bored out to 3 1-16 in. radius, or equal to 6⅛ in. diameter, this being to accommodate a brass liner which has a bore equal to 5⅛ in. diameter.

The liner however is of half circle section, and goes to the bottom only. The cap has no liner, and is merely bored out equal to 5⅛ in. diameter. The reason no liner is placed in the cap is as follows: All the wear is downward on these bearings, therefore there is no need of a liner where it would never wear out. The method of supporting the work shown at Fig. 3. is

FIG. 3—DRILLING THE CAP HOLES ON ONE OF THE TABLE SECTIONS.

readily seen, so that no comment is necessary.

The next photograph Fig. 5 illustrates a few of the rolls going to make up one of the tables. The turning work on the rolls alone is a considerable item, and the few figures to follow will be of particular interest. The approach table, as made for the mill we speak of, has some forty rollers, ten table beams, seventy bevel gears of thirty-three teeth, 1½ D.P., and other numerous parts of like importance. The front mill table has twenty rollers, and the rear mill table contains a like number; 42 mitre gears go on each table, and all drive gears are keyed to shaft with two keys and coupling gears are held in a similar manner, but the roller gears have only one key. The rear mill table is driven with two 80 H.P. motors, and is also the front mill table.

Run out table has 58 rollers, and it might be well to add that these rollers are 14 in. diameter, 5 ft. in length of rolling surface, and 7 ft. 9 in. overall. The borings are 4½ in. and 5⅛ in. in some cases. Steel castings of course enter largely into the construction of these parts, although the caps for roller bearings are of cast iron. The motor drive gears on some of the tables are 29½ in. outside diameter, 87 teeth, 5 in. face, and 3 D.P. These gears are cast steel.

The run out table has two 50 h.p. motors to drive it, and the hot bed table has a similar equipment. The hot bed table has a grand total of 61 rollers. The reason these hot beds are made so long is in order to allow the stock to cool, much as this may sound contradictory. In other words, the hot bed is a resting place for the stock while it is cooling.

The keyways used to hold the bevel gears to the drive shaft are 1¼ in. wide, and two are used. The shaft for approach table is 5 in. diameter at the largest part, and is over 12 ft. long. As stated previously, all sections are aligned and keyed together, and this must be done accurately. Every bolt hole is spot faced on these tables and all bearings are specified on the drawings as follows: The shaft must have a perfect bearing over its full length.

The charging furnace pusher itself is an intricate piece of work. Most of the mechanism is underground, but roughly,

FIG. 2—SIX SECTIONS BEING PLANED ON A LARGE PLANER.

FIG. 4—MILLING THE ENDS OF A SECTION ON A LANDIS BORING MILL.

here is what occurs. A horizontal skid motion is developed through a lever and sliding arm, this pulling the billets over to the furnace. Two 20 h.p. motors drive the arrangement and there are over 14 gears in the mechanism. There are various 118T—2D.P. herringbone gears used in the discharge pusher, which is, of course, the reverse idea of the furnace pusher, insomuch as the discharge pusher takes the billets away from, and not to, the furnace.

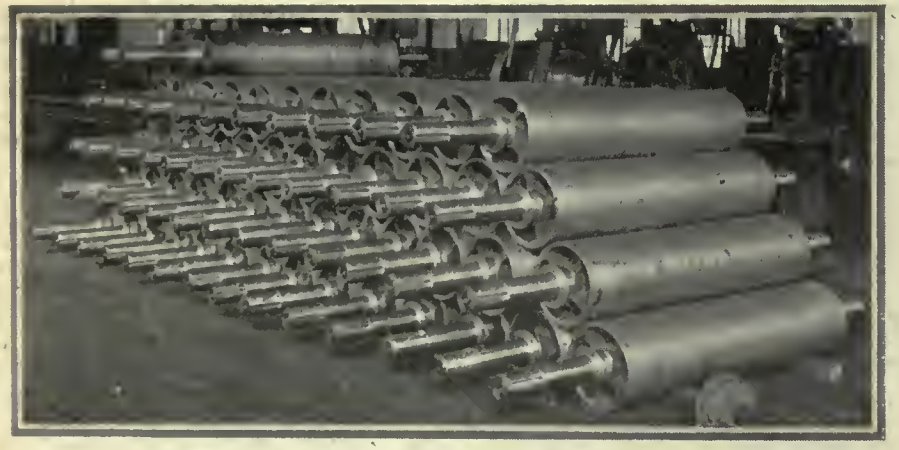

FIG. 5—A FEW OF THE ROLLS GOING TO MAKE UP A TABLE.

It can be easily understood that no sequence of operations can be given in an article of this kind owing to varied parts being made, but enough to say that other parts almost innumerable enter into the makeup of such tables. These include roller plates, lock washers, cap bolts, bracket bolts, nuts, keys, thrust collars, oil rings, gear guards, separator bolts, bearing caps, etc., etc.

The work entailed in the preparation of tables is surprising, one particular table being more than 145 ft. long. There is over 550 ft. of table space up to the shear delivery table alone. This is a new industry for this section of the country, and necessitates both a need of accuracy and a keen knowledge of requirements. The mill for which these tables are being made is of the Universal type, and can produce billets, blooms, sheets, bars, narrow universal plates, etc., etc.

Rubber Mill Work.

Leaving the work on plate mill at this point, let us next consider the variety of work being accomplished by this concern for rubber working plants throughout the country. A sample of such work forms the title piece of the present article.

This view depicts the machining of a large ram for a special vulcanizing outfit. The work is 22 in. in diameter, 17 in.-5 in. long, and has a screw hole in one end that is threaded for a 4 in. taper plug. The other end has three ribs cast into it, spaced 60 degrees apart. This work must not only be machined but must be polished and free from scratches. There are also four 1 in. holes drilled at the webbed end of roll, and these holes are drilled to a depth

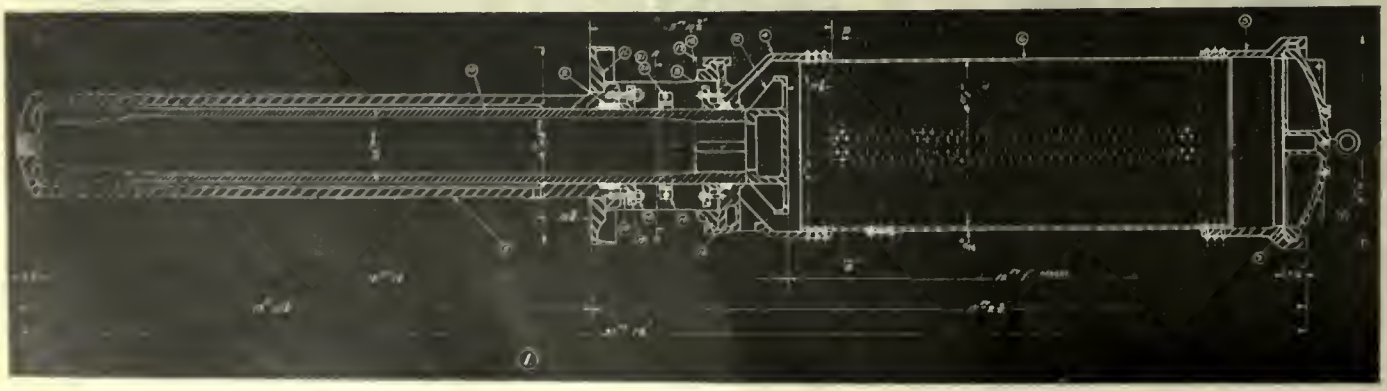

FIG. 6 SECTIONAL VIEW OF 48" VULCANIZER. TEXT EXPLAINS THE METHOD OF OPERATING.

LEFT HAND VIEW FIG. 7—THIS SHOWS A MOTOR BED PLATE BEING MACHINED.
RIGHT HAND VIEW FIG. 8—AN INTERESTING ASSORTMENT OF TIRE MOULDS.

of 21¾ in. The work on the latter operation is performed on a Landis boring mill. There is approximately 1¼ in. to 1½ in. to come off the diameter of these rams, in order to get to the perfect metal. The work is accomplished on a 33 in. Le Blonde lathe and takes approximately 50 hours to complete.

Let us next consider Fig. 6. Here we see a sectional view of a 48 in. vulcanizer that this concern recently completed, and a short description of same would not be amiss. The tires are placed in the chamber shown, top lid is closed, and pressure put on the ram. The ram is 22 in. diameter, and has a hydraulic pressure of 1500 lbs. per sq. inch. The steam pressure used is 40 to 50 lbs. to the square inch. The stroke is 12 ft. 1 in. and the top lid is arranged with a special breech block lock for quick handling. The machine work necessary on a vulcanizer of this nature is easily seen by reference to the sketch.

The planer job shown at Fig. 7 is one of rather decent size. It is a motor bed plate for a 400 H.P. rubber mill line, and the base of the piece is approximately 7 ft. square, the height being almost 3 ft. As will be noted there are four heads to the planer, and use is made of all four whenever possible. In the picture shown only two are being used. The bottom is first planed, then it is turned over, and top is completed. The piece is next turned round and the edges planed. This bed plate is made of cast iron, and the job is completed in approximately 30 hours.

Another interesting photograph is that at Fig. 8, this view showing an assortment of tire moulds. This concern makes practically any type of mould, but the style shown is a collapsible core, for straight side tires. Note that the

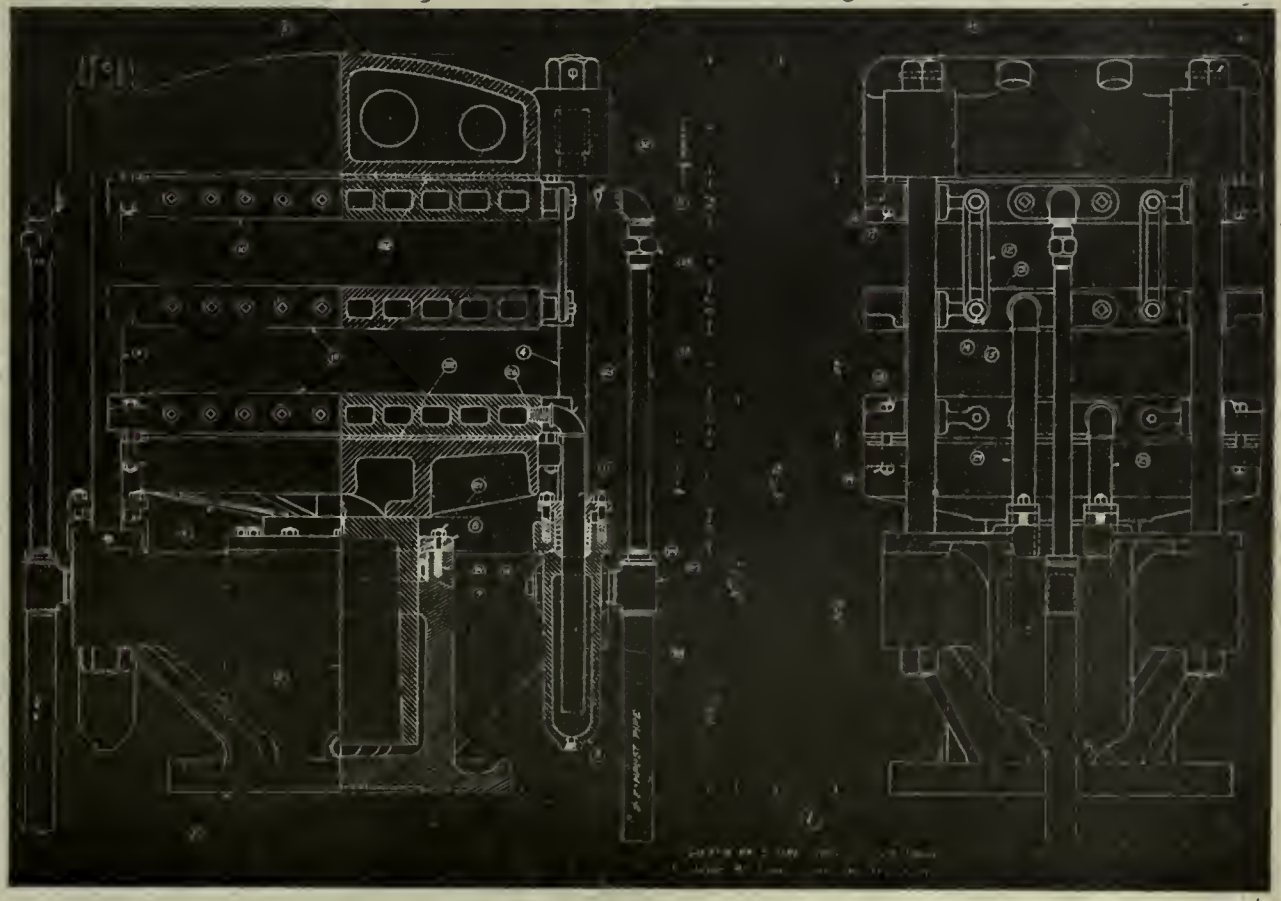

FIG. 9—A 75-TON 36" x 36" HEATER PRESS RECENTLY COMPLETED.

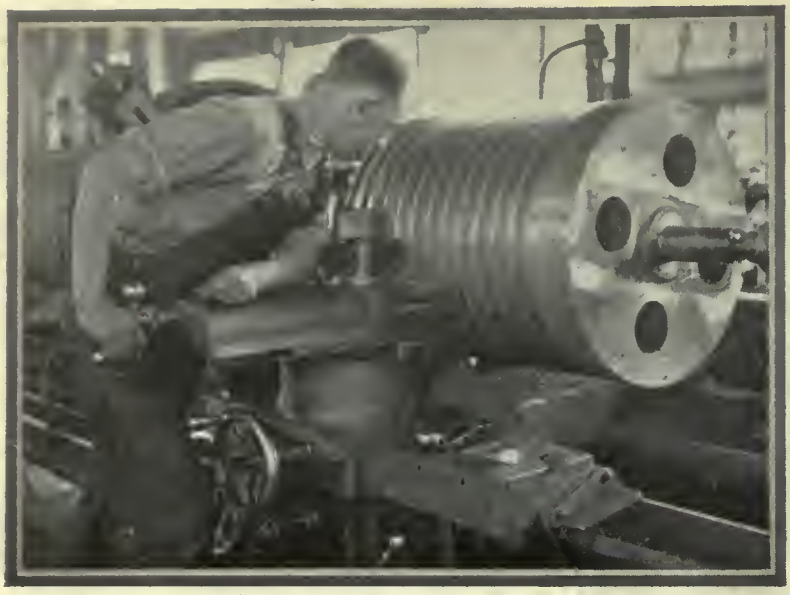

FIG. 10—MACHINING A BEAM ROLL FOR WIRE ROLLING MILL.

ring with bolts holds the two sections together. The machine work on one of these moulds is self apparent. The majority of the operations are completed on vertical boring mills, and of course all work is held to templets. This concern also does considerable tire mould engraving, and the engraving machine used is of unique design. Any style of tread can be arranged for, and engraved into the mould. Some very interesting treads were shown the writer, and the information was given him that there was not any impression they could not do on these machines.

The next illustration, Fig. 9, depicts a 75 ton 36 in. x 36 in. heater press. This has two six inch openings, and the steam platens are so designed as to be interchangeable. This means that only one spare platen is required in place of the regular three. The steam chests are also interchangeable, and this press has a water pressure of 1,000 lbs. per square inch, and a steam pressure of 40 lbs. per square inch. The steam of course is used to keep the platens up to the correct heat for vulcanizing. They are used for various kinds of rubber goods, in addition to bead molds for tires, and this short description will be sufficient for illustrative purposes. In conclusion we will generally summarize the varied class of work going on at this plant.

Fig. 10 depicts the machining of a beam roll for wire rolling mill. These rolls are 24 in. in diameter, 11 ft. 8 7-16 in. overall, and have 66 grooves and 15 ribs in their finished state. The grooves are 1 11-16 in. wide and the ribs 5-16 in. wide. The very fact of these ribs being so narrow necessitates great care to prevent the breaking of the same during the process of machining. The grooves are 1¼ in. deep, so that considerable machine work is necessary.

Following is the method adopted in the machining of these rolls. The first operation consists of taking a roughing cut across the complete roll when it is now removed from the lathes for the purpose of balancing. It is placed on straight edges for the purpose, and is balanced by means of sticking clay on the light parts. After sufficient clay is placed on the necessary portions of roll it is weighed and the amount of offset computed to balance roll when turned. When this is done, the center is drawn over, the work placed in the lathe once more, and turned to within ⅛ in. of its finished diameter.

A square nosed tool is next used to rough out the 66 grooves, these being cut down 1 3-16 in. deep. The steady rest is placed in its correct position and the ends bored out. First, the hole is bored for bearing spindle at the carriage end, after which work is reversed and used with steady rest at end as before.

The remaining end of work is now bored out, and the regular bearings driven into place. After the first side has been bored, the regular center at headstock is knocked out, and replaced by a bell center of suitable shape to accommodate hole previously bored.

The bearings being driven in, the work is completed on centers as shown in the photograph, and all grooves are carefully finished. This work is also accomplished on a 33 in. Le Blonde lathe.

TURNING OUT SMALL MOTORS

Continued from Page 587

The work performed is the punching and blanking of field cores, and one of the completed disks is shown at A. The punching, taken from the centre, is shown at B, while C depicts an assembled field core. Both the die blocks and punches are made solid in this case, but of course the four small punches are separate as can be noted. The same style gauge is used, and the procedure of making the die being the same as already described, we will pass on to Fig. 13.

Fan Punching Die

In the make-up of the Hoover suction sweeper, there is a fan used to keep the motor cool. The die used to punch out this fan is shown at Fig. 13. This is an intricate piece of punching, and each of the web-shaped punches A are made separate. The centre punch in this group is of course also a separate punch. The blanking punch B is solid, as is the die block itself. A completed punching is shown at C. Following up this fan, let us refer to Fig. 14.

To the left of this picture is depicted the die used to form the blank made at Fig. 13. A represents the punch, with pilot attached, B the forming die. At C is shown the flat blank, D depicts the formed fan, while F shows this fan mounted in its hub. The punch for forming is made solid, but the pilot punch is separate. As before, the die block is solid. The forming portions of the die operate from a spring stripper underneath the lower bolster plate. The action can of course be understood. The blank is placed on the die, down comes the ram and the stock must naturally form the punch and die, being formed to the shape shown.

The die to the right at Fig. 13 shows the equipment used to complete the contact arm of a motor. One of these arms can be noted at F. The peculiar shaped main punch measures approximately 2 5/32″ across, so that this measurement will allow readers to form a good idea of the proportions of the rest of the die. The smallest punches on this die are only .050″ diameter, and the others are 3/32″ diameter. There are also 2 oval punches as can be noted. The work on this piece is rather delicate, and mechanics can appreciate the fun in making punches .050″ diameter, not to speak of the tempering of the same.

Having touched on some of the important dies as used in this class of work, let us in conclusion consider the life of such dies. Take for example the die shown at Fig. 5. Here we have a double armature die of intricate design, yet 12,000 to 16,000 punchings can be made between grinds. The life of the die is clearly shown at Fig. 9 and a very conservative estimate could be placed at around the one million and a quarter mark. Some dies are ground from seventy to eighty times, or in other words, reduced from their original 1⅛″ thickness to ⅛″ thickness. The solid punches have also been found to stand up in like proportion. Such figures tell more than appears on the surface, and although the small clearance of .003 per side is not universal practice, it is the very fact of their using this clearance that makes for the long life of the die. Were the clearance greater the die could not be ground as far without affecting the character of the work. The experiences stated herein are definite and authentic, and deserve careful consideration.

Taking the *Dust* Out of *Industry*

Rewarding Honest Effort Is the Basis on Which Success Can Alone Be Secured—How One Firm Is Dealing With Matters of Employment, Good Conditions and Fair Pay

WHEN a person mentions bonus systems to encourage production there comes to the mind the history of the old piece-rate work, and there are not a few people who make a face when that is mentioned. The old piece-work shop was a queer proposition in some ways, and even yet it is hard to figure out how some of the men who operated them convinced themselves that it was good policy to set a piece-work rate, and then, when a worker got to the point of efficiency where he could pile up a decent pay envelope, cut the rate and start him all over again.

Well, a real bonus system is a different thing; at least it is in the shop of Robbins & Myers at Brantford. This firm has been making small motors at the parent plant in Springfield, Ohio, for a long time, and in March of 1920 they were ready to start operations in the Canadian field, following out here many of the ideas and plans that had worked successfully in the other place.

Robbins & Myers believe in bonuses. They believe in paying for service rendered. They believe in their employees making good wages, and they believe in keeping their hands as long as possible. But at the back of all this is the one thing that makes the rest possible, viz., when they set a price on a piece of work, they will not cut that figure because an operator or a mechanic can make good money. The only thing that would lead to the change in a price is when the operation is changed, or where it has been found in actual practice that the price on a new piece of work is at fault.

Mr. Roy Booth, the manager of the Canadian plant, makes this point very clear: "Were we to cut a price that we have set, our whole system of bonuses would go to pieces, and the employees would lose confidence in us." That, in brief, is the way he regards the bonus plan.

"In the old plan of day work, and often in the old days of piece-work, people did not know what their product cost them," continued Mr. Booth. "You know what used to happen in the piece-work. An employee would study every movement and cut out every detail of waste in the operation, and by hard work he would become so efficient that his wages would grow, sometimes over that of the foreman, or many of the people in the lesser executive positions. Instead of patting that man on the back and telling him to go ahead, there used to come the cut to a figure that would make it a killing job to make a decent wage. The idea was wrong, all wrong, and the wonder is that even yet we have some shops that follow this practice."

Pay for Production

The Robbins & Myers plan of pricing work is reasonable. There is nothing that points toward the sweat shop tactics. For instance, if 60 units is a fair amount of work for an hour, and if an operator, after becoming skilled, can put 80 or 100 or 120 units of work into the same period, is there any good reason why the reward should not increase in proportion? None that we can see, and the Robbins & Myers people figure it out the same way.

In the making of these time standards, care is taken to be reasonable. The operator who does the work when the time is being taken on the piece knows that he is being timed. Then the same operation is timed again, and allowance made for the delays that invariably come. The standard set is aimed at being as near reasonable as possible, and if there is any work where it can be shown that the rate is not fair it is reconsidered.

When, for any reason, that the operator cannot control, production is held up, the company pays for the time on the basis of the 60 units.

There are Exceptions

Just a few weeks ago some new stock was taken in. In this case it was largely for grinding and drilling. The stock that had been in use previously was particularly good and there was a uniformity in the steel that made it very easy on the tools. When the new stock was put in a change was found. It was a different thing. The steel was hard, and a person working there could hear the tool grinding and cutting as on a piece of flint. There was need to take the tools to the grinder more frequently, and there was quite a difference in the speed

THE CANADIAN PLANT OF THE ROBBINS & MYERS CO., AT BRANTFORD. ALTHOUGH THE BUILDING HAS BEEN COMPLETED ONLY A SHORT TIME, SPLENDID PROGRESS HAS BEEN MADE IN BEAUTIFYING THE GROUNDS AT THE FRONT, FLOWERS AND SHRUBS MAKING A PLEASING SHOWING.

with which the operation could be done. That was adjusted just as soon as the operator and the foreman found that there was a change in the steel from the quality used when the work was timed in the first place. A new timing was made, and it will remain there until the harder stock is run out.

The Inspection Department

Well, if the rate is good, and there's plenty of work, why not steam ahead and get rich? Simply because there is an inspection department on the job to see that quality survives along with quantity. There are the floor inspectors and the bench inspectors. The floor inspector has to see that work is being made according to drawing, and that end comes under his notice. He is paid on the output of the department—that is, his bonus rests on that. But of course neither he nor the workers in the department are paid for work that is rejected. Then the bench inspector has a peculiar undertaking in that he is paid more for detecting a poor piece than he is for passing a good one.

"Well, hold on," I broke in here, "will that not mean that a bench inspector would be in a poor way financially were the work of the whole department brought to such a high standard that there would be very few rejections?"

"It might work out that way were we to let it go at that," replied Mr. Booth, "but we look after the bench inspector in other ways, and he is not allowed to go poor because there are few rejections. It has been our experience that the system brings the operators, the floor inspector and the bench inspector together to get the best results for all, for it is in completed and accepted work that the payment is made. There is very little work thrown out now, and very seldom is there any dispute over the matter. I am certain that I have not been called in to settle any such matters since the establishment was opened in Brantford."

The Securing of Help

Do they have trouble in securing help at the Robbins & Myers plant? They do not, and neither did they when help was scarce some months ago. The situation was not quite similar then to what it is to-day, when men and girls are looking for work. At the start of the year they were in need of help. They were not known in this country, and people who might be looking for employment were not "sold" on their shop. They are now. But to get back to the start, Mr. Booth practically tapped a new labor market in a new way. He wanted girls to work principally in the winding department, and he advertised. But he did not stick in a little two or three line ad. stating that they wanted a number of hands. He went about it in another way. He stated in his advertising matter that his firm would be ready to commence work in a short time, and that girls desiring to secure employment should call and receive an employment application form, which they would be required to fill in, and on this they would need the signature of two reputable business men certifying to the standing of the applicant for employment. Did the girls in the community resent this? Not a bit of it. They came along with their application forms, and they secured employment, and, what's more, they liked the place, and stayed with it. In the little strip photo published elsewhere in this article are some of the first girls who came with the Robbins & Myers plant. Some of them have left since the photo was taken, but they had very good reasons for so doing, and their leaving only goes to show that no matter how good your system of employment and treatment, it is liable to be broken down now and then. Dan Cupid is the chap who made the break here and the girls are now keeping house in Brantford.

Largely Skilled Help

Now don't get the idea that girls form the majority of the help employed at the Robbins & Myers plant. They have a highly organized plant for the manufacture of small motors, and in it have a large number of highly trained men, and it is through all the plant that the system of bonus and other forms of reward is in operation. The firm operates an open shop, but there are union men working in it.

Mr. Booth, as far as one can judge, can see no difference between the office and shop, and the chances

THE CAFETERIA IS SELF-SUPPORTING, BUT NOT A MONEY MAKER. THE REST ROOM IS A QUIET, COMFORTABLE SPOT, MODESTLY FURNISHED.

are that this doctrine is pretty well understood around the whole premises, and after all his way of figuring it out is right. Here it is:

"Every operation that goes on in this plant, whether it is in the office or the shop, or on a truck, is necessary. That is the point from which we start to work, and we try to keep before every employee the fact that all are needed and all are necessary, and that one department cannot get along without the other. We are succeeding in doing this, and there is not a regulation that applies to the shop that is not in force in the office."

I remember being in Mr. Booth's office some months ago when one of the employees came in and told him that a number of them, from either the office or some corner of the shop were having a corn roast that evening and would like the use of the cafeteria for a dance after the corn roast.

"First rate," responded Mr. Booth, "by all means have your corn roast, and by all means have your dance after it."

The employee thanked him, and was just about to withdraw, when Mr. Booth started in again: "But remember this, that when you come here and open the cafeteria for a dance in the evening, it is open to all the employees of this company and not to any particular few. If others who are not invited to the corn roast happen to be along here during the evening and see the cafeteria lit up and ready for a dance, it must be understood that they are just as welcome as the party holding the corn roast."

The corn roast was held and the dance was held, and, in the words of the country correspondent, "a good time was had by all."

It Pays do Do These Things

The Robbins & Myers Co. believe in time clocks—in fact they are all clock punchers. There may be some who escape, but I have not heard of it. And the strange thing about it is that they are keen to punch the clock, four times a day. It pays them to do it; not that they are penalized for not doing it, but rather they are rewarded if they attend to this promptly.

There's a bonus for the punchers, and the good punchers can punch out a five per cent. bonus for a week's good performance. So if a girl makes $20 a week she can add a dollar to it by simply punching the clock promptly morning, noon, and night. If a mechanic makes $30 he can add $1.50 per week in this very simple manner.

"And what per cent. of the employees are bonus punchers?" was asked.

"Oh, at least 95 per cent.," was the answer. "We make no allowance on this, and there are no excuses accepted. I remember not long ago that one of the officials here stayed until 6.30 in the evening talking to a customer from out-of-town. When he went out he forgot to punch the clock and it spoilt his week. But we have to make a hard-and-fast rule in this matter, because once it becomes known that there is a single exception made to it, your whole system is off and done for. The bonus for a perfect week is paid on the total earnings for the week, including any production bonus that may have been earned."

And the company admits that it pays to take this positive measure of rewarding good attendance rather than by taking the negative view and penalizing for slow arrival, and the result is that the employees are all on good terms with the time clock.

Then There's a Service Bonus

The Robbins & Myers people are anxious to do away with their labor turnover as far as possible. In their line of work, as in many others, the longer a person is with them the more valuable they become, and the more the company desires that they should continue. In order to get this they use a service bonus. It's not a complicated piece of business, and works out something like this:

When an employee has been with the firm for six months his bonus starts, and at that time it is 1½ per cent. of all the money he has earned in the previous three months. This keeps on until at the end of five years, the increases coming every six months, the employee finds that ten per cent. of all earnings in each previous six months are handed to him in a lump sum. This bonus includes ten per cent. on everything, even to the five per cent. bonus that is paid for prompt attendance and punching of the clock.

"Well, does it pay to go that strong?" was asked of Mr. Booth.

"There's not even room for an argument about it," was the answer. "It has almost eliminated our labor turnover. It holds our employees here, no matter how hard other firms may try to get them. We know how our wages compare with others paid in various shops here, and when there is, after five years, a ten per cent. bonus every three months, do you think any man or girl

A Word About Mr. Booth

ROY BOOTH.

Roy Booth, works manager of the Canadian plant of Robbins & Myers, Ltd., is not a theorist alone. He knows what a fair day's work is, because at the age of 15 he started as an apprentice with the Dayton Brass Co., where he served his time, upon completion of which he went as a bench mechanic to the American Tin Can Co. Entering the plant of the Dayton Computing Scales Co., he worked up to the position of assistant superintendent, and in 1908, when the branch was started on Vincent Square, Vauxhall Bridge Road, he was placed in charge. In 1910 he came back to the Dayton plant, remaining with this same company until 1917, when he entered the employ of the Robbins & Myers Co., at Springfield, Ohio, first as chief inspector, then as assistant electrical superintendent. In September of 1919, the company informed Mr. Booth that he was to be the man to head their peaceful invasion of this good land to the north. Work was started on the Brantford plant in October of 1919, and in nine months the plant was complete, machinery placed and running, a staff trained, and production of 150 motors per day was secured.

Mr. Booth is making a pretty fair Canadian. He can't swallow his accent yet and it continues to come to the top of his vernacular. Rotarians and other good chaps at Brantford have taken kindly to him—they like to have him about and vote him a good citizen. His wife holds much the same views and two young Booths claim the privilege of calling him Dad. He likes Brantford and Canadians in general, and it looks as though he were planted up here for keeps.

is going to pass that up without a little more than passing thought?"

Come to think of it, the thing works out to a nice little item. For instance, suppose you were working for the Robbins & Myers Co., and had been there for five years, and were receiving the ten per cent. bonus. Your wages are, supposing again, $40 a wook—not an unlikely figure—that would be for thirteen weeks, $520. Forget the clock bonus for the time being, and think only of the $40 a week. Well, around Christmas, or around anything else for that matter, it would not be a bad sensation to have an extra cheque coming across for $52, and it would be a still more pleasant sensation to have this happening every three months.

This service bonus applies to every person in the establishment, office, tool room, winding department, shipping, trucking, etc.

Some Ideas of His Own

Mr. Booth, the Canadian manager, has some ideas of his own in regard to the handling of a staff, and I remember quite well that on one occasion he discussed this matter, although he was not speaking for publication at that time. But the idea is a good one and worth repeating:

"I do not like to see a man leave here, and I dislike still more to see a man or a girl discharged. We try to find a place where they can make good. I make it a point to see every person myself who is leaving our employ. There are cases where men leave machine shops and foundries because they are not getting a square deal from the foreman. I have run across just such cases; not here, but in other works. A workman may be 'in wrong' with the foreman, and it is a very easy matter for the foreman to give him all the lean jobs if he is on a bonus basis, and make it almost impossible for him to get ahead and make money. If a man leaves this establishment for a fault that is not his own, I think we are entitled to find out just where the trouble is, and if it is ours we want to set it right, and if it is his we want, if possible, to set him right. A great deal can be accomplished with a little good sense and reason, and the more you deal with men the more you should know about them. There are often cases where a man will not take his complaint over the head of the foreman or the superintendent: he will simply pass in his slip and fill out a quit card rather than make a show for it. He leaves, and gets work elsewhere, but he is very apt to entertain a poor opinion of our works, and this can be very easily spread. When this is going on to any great extent you cannot keep the community 'sold' on your shop being a good place in which to secure employment."

Every employee who takes employment with Robbins & Myers is insured with no cost to the individual under their group insurance system. It starts at $500, and increases $100 each year until a maximum of $1,000 is reached. If, through illness, the employee has to leave work, the insurance continues, and will be carried, if necessary, for a term of twenty years, provided of course that the insured person does not accept employment elsewhere in the meantime, in which case the insurance ceases. This insurance feature is a popular one with the employees, as they are glad to get the added protection and are apt to think seriously before leaving the employ of a shop extending them this amount of free protection.

Some months back now it was decided to put in a cost-plan cafeteria. The building was constructed with this in view, and the cafeteria is over the office. The floors are of hardwood, highly polished and waxed with a view to using it for dancing purposes. The tables and chairs are so made that the entire floor can be cleared out.

"Make much out of the cafeteria?" we asked.

"Sure," laughed Mr. Booth. "For the first three months we were $7.93 ahead of the game, and I have just received the figures for the last month which show a profit of $1.96, and you know that could be very easily wiped out if one were to let the knife slip a couple of times in slicing up the ham at present figures. We post a statement every month so that all the employees can see it, showing what we have in stock, what we have paid out in wages and for provisions, and against this what we get in the way of receipts. This has worked out very satisfactorily, and we are able to keep the confidence of all in the prices that we charge for the service."

Then there is the first Saturday in each month. It may be known locally as Fox Trot Saturday or Barn Dance Saturday, but whatever the name, on the first Saturday evening of each month the company opens the cafeteria in the evening for the employees to have a dance. They can bring along their friends, apparently the more the merrier. Where does the company come in? They do everything but dance. They provide the dance hall, the music, the cake and the coffee, and it is not on record yet that they have squealed about the number of friends that any employee leads out. The office staff and the shop mix freely at these gatherings, in fact there is no distinction one way or the other.

Sports are encouraged, and the Robbins & Myers team won the soft ball championship of the city in 1920. There is a clean, wholesome air about the whole place, and the evident desire of the company is that its employees shall make a good living and have a fairly decent time while they are doing it.

Judging a Wheel

We often hear the query what is a hard wheel and what is a soft grinding wheel. These terms are rather confusing and are not really comparative terms.

A wheel may be too hard for one job and too soft for another. If a wheel is too hard for one job, its bond insists on holding onto the abrasive particles after they have lost their sharpness or cutting power. Such a wheel is very inefficient and will glaze badly. If the wheel is too soft the abrasive particles will break away from their setting in the bond before they have lost their cutting power. Such a wheel wears away very rapidly, but on the other hand, it cuts very well. The ideal wheel is the wheel with a bond that permits the abrasive particles to drop off and expose new particles just at the point where the old ones become dull. With the wide variety of grits, grades and bonds manufactured, it is possible to purchase a wheel with just the right characteristics for most any job.

THESE ARE THE FIRST GIRLS COMING TO THE ROBBINS & MYERS PLANT WHEN OPERATIONS WERE STARTED. EXCEPT FOR MARRIAGES THEY ARE STILL WITH THE COMPANY.

Works Council After *Two Years'* Trial

PLOW WORKS
HARVESTER WORKS
THE INTERNATIONAL HARVESTER COMPANY OF CANADA, LIMITED — THE LARGEST AGRICULTURAL IMPLEMENT WORKS IN THE BRITISH EMPIRE

ALMOST two years ago the International Harvester Co., Hamilton, started the Industrial Council plan in their establishment, doing so on a favorable vote of the employees. Their evidence in the matter is valuable now because it has the weight of real experience behind it. Canadian Machinery found officials of the company very frank in discussing the system, and anxious to give other manufacturers the benefit of the experience they have had in this direction.

MANUFACTURERS are trying to find some plan that will put the "US" into indUStry. The men in the shops are ready to meet this idea half way. No man likes to feel that he is working in a shop, and yet is not part of it. There is something in the make-up of the average person that calls for a "say" in the conduct of anything that he is connected with. When one can satisfy that feeling, and link up with it a force that will actually make a man a better and more competent workman, then the chances are that you have something worth while.

Now that's just about what the Industrial Council is doing. It is not a matter of theory any longer. The average manufacturer or employer is not much impressed with theories now. He has seen too many of them flivver—but he is interested in anything that will work when it is put up against shop conditions for six days a week. The Industrial Council started as a theory, and it is now established as a fact. The International Harvester Co., at Hamilton, have been operating under the Industrial Council plan for almost two years, and they are willing to continue it. Nor do they hide their light under a bushel. As you enter the premises at Hamilton you are informed, by means of a large notice, that this establishment is operated under the Industrial Council Board, and when you reach the large offices upstairs there is another indication in the form of a commodious board room, devoted to the affairs of the Industrial Council.

The International Harvester Company believe that this system has gone past the experimental stage. They are willing to admit that it is a success, and are satisfied that conditions are better all round. It is almost two years since the plan was inaugurated. The secretary of the Works Council devotes his entire time to its working, and he has plenty to keep him busy, for the work grows in new directions every month, and the idea of "doing things" seems to be breaking out in new places all the time.

Here's What It Does

If you had a system in your shop that would make a mechanic a better mechanic, or that would cause a moulder to be a better moulder, don't you think you would be satisfied that you were working along the right lines? Well, there's no revolution going on at the Harvester plant, but it is a fact that the work that is being done through the Industrial Council plan, is doing this very thing. For instance: Some dispute arose in the foundry about the rejection of castings, and the matter was taken up at once by the elected representative of the men in that department. But it never got to the Industrial Council, nor is it recorded that there was even a special session about the matter. How was it done? Simply this: The men in the shop looked into the matter, and they found that the work that this particular man had been turning out had not been up to the quality required by the firm. They went right to him and showed him how he could improve his work a great deal, and make more money by so doing. What happened? Why only one thing could happen. That moulder began right there and then to do better work, and that was the end of the complaint and of the whole matter.

The Works Council, if I get the thing right, does not aim to have a truck load of complaints and squabbles to deal with when it comes to its monthly meeting. Rather is it considered a good meeting when there are none of these matters to come before the board, and where the whole time can be taken up in planning new things and better methods.

Of Course There Are Wages

Canadian Machinery discussed the working of the Council with the Works Council secretary at some length, and in response to a query about the most-discussed thing dealt with, the answer came in the form of an admission that wages crowded pretty well to the top of the list.

"And can you come to an agreement about wages?" was asked, for it is a fact that hardly any man ever thinks he is regarded financially high enough by the firm for which he works.

"When we get together on this ticklish matter of wages," answered the secretary, "we find that the men are not unreasonable when they have all the facts placed before them. Of course we try to have as many real figures as we can when we discuss these matters, and it is our desire to bring our statistics as near correct as possible when we come to discuss the cost of living in Hamilton and else-

where, for that is what most of the demands for wages are based upon."

The secretary admitted that they did not accept the Ottawa figures, nor yet did they rely on the figures gathered by their branches in United States. "All these are good enough, but when our men are living in Hamilton, and keeping house here and buying their stuff here, this is the place where we must base our figures if they are going to have a real weight with the men, and going to be fair for all parties concerned."

And so the Harvester people took a very real way of finding out what it cost to keep house in Hamilton. They took a family budget, not one that a bachelor might think necessary, but a real one, worked out in the council from figures from real Hamilton homes, and they had the purchases made in the stores where their men dealt. The idea was to get as near as possible to real facts, so that when a readjustment of wages was made it would represent the real burden that was going to be placed on these wages when they were spent.

It took some little time to get this family budget brought as near correct as we wanted it, but in the end we found that the figures as worked out by the company, and the figures prepared by the men were just 38 cents a week apart for a family of five, so it was not a very serious matter to get over that difference."

Well, Not Yet

"Any cases yet that the Council have not been able to settle?" "Not yet," was the answer. "The principal thing in settling cases is to make sure that they go through the proper channels in the shop, especially to the foremen, before they are ever allowed to come before the Council. We do not want them brought in here for discussion or settlement. The Harvester Industrial Council makes provision for disputes being discussed in the shop and never brought in here at all, and we encourage that. Some of the men's representatives in the shops are very capable in the role of negotiators. We do not claim that there will not be questions coming up that we cannot handle, but we do know that more and more there is being created a get-together feeling in the works, and men who were hostile at the start, or luke-warm at least, are being won over to the proposition."

"Any particular instance of this, or just a feeling in general?" "Yes," went on the secretary, "here's a particular case. One of the foremen was very skeptical about the whole thing, and he was not in sympathy with the move. It may be that he thought matters would be carried over his head by the shop representative of the men. Well, we asked him to come in one day and attend a meeting. He did, and heard all the discussions that went on, and had an opportunity to see for himself what there was in it for the men and for the company. When the session was over he told me he was sold on the idea. He had not understood how it would work out before. Since then he has been one of its best friends, and does all he can in the shop to see that the Council has fair treatment there.

Feel They Are In It

"Let me put it this way," I suggested. "Are there any results now, that you did not look for when the plan was first put into operation?"

"One big one," was the secretary's opinion, "and that is the men have the feeling that they now have a say in matters around here that would not be possible in any other way. That in itself is worth a very great deal and something many manufacturers are very anxious to secure. There is nothing a man values more than the feeling that he is really part of the works, and has a voice in the direction of the concern."

Nor does the work stop here. There is a mile or so more things than simply attending to the conditions in the shop. Did you ever get a new job in a big shop in a strange city? Not a particularly desirable sensation sometimes. You wondered who the chap next to you was, and perhaps didn't like to ask him. You didn't know where things were, and you felt generally strange for a time. Well, how would you like to have some one come along the first morning and give you a hand shake, and make you feel at home—tell you the run of the place, and everything you wanted to know—make you aequainted with the man on the next machine, tell you where the cafeteria is, and give you an idea of the run of the day, and what was going on around the place. Not bad, eh? Or if you were laid up for a day or so, you used to wonder if your little old job would be waiting there for you when you got back, or if you'd have to start in again all over. Mueh better to have some one from the shop call at the house, and see how you are getting along, see if you are getting proper attention, see of there is anything they can do for you. Why, of course. Well, that's the sort of work the Council encourages, and when a body of men get headed in that direction it's hard to say just when or where they will stop.

The Cost Plan Cafeteria

The Harvester cafeteria is a busy and popular place at noon hour. Realizing the important bearing a hot meal has on the workers' health and efficiency, Works Council petitioned the company for space and equipment to establish a cafeteria, which they did, setting aside a large floor on one of the existing buildings, and installing a complete modern outfit, then the project was turned over to Works Council to operate for the benefit of employes. There superintendent and janitor are all served alike with a substantial plain hot meal, as well as cold service at cost, and

These Views Tell of Happy Days at Harvester Picnics

The Plowites' Band is an Ever Popular Organization

wherever it is found possible to reduce prices it is done at once.

The Harvester Company in all its plants has a benefit society to which both the employe and the company contributes. It costs the company something like $50,000 per year for this work in its various branches. A man is entitled to 50 per cent. of his wages when sick, and this will be paid for 52 weeks. In case of death the heirs receive the equivalent of one year's salary of the deceased.

They also have in operation a Pension Plan, the expense of which is borne entirely by the company, and which is purely a voluntary expression of the company's desire and purpose to stand by the men who have stood by it, not as pensioners, but as the company's old guard, who have well earned this reward for long and loyal service and are justly entitled to all that the company does to make their lives happy and more comfortable.

Employes are pensionable at 65 years after 20 years' service, at 60 after 25 years' service, and at 55 after 30 years' service. Women are pensionable at 50 after 20 years' service. Special consideration is given to employes whose age and service approximate this requirement, and who become totally and permanently incapacitated.

There there are other directions in which the Council find room to work. The first aid class is an efficient body, although fortunately their services are not called upon very often, as the works at Hamilton have been fairly free of serious accidents for some time. This may be partly due to the fact that suggestions are welcomed at all times regarding safety appliances, and improved methods for doing any operation. Directly across from the main office is the hospital for the works, where a doctor and nurse are in attendance.

The same committee that looks after the cafeteria, health, etc., have charge of such affairs as gardening and the beautification of the grounds of the homes where the employes live, and they hold to the belief that a man is a better workman if his surroundings out of the shop are bright, pleasant and congenial. During the last season there were some 275 garden plots provided by the company, in addition to a contest between all the Harvester plants for the best kept gardens at the homes of the employes, two Hamilton gardeners winning the third and fourth places. Other committees look after publicity for anything and everything that goes on in connection with the work of the Council around the plant, in connection with social gatherings, sports, picnics, etc. Very useful work is done by a committee that looks after the sick of the shop. A list of these is furnished to the committee, and a point is made at once of calling on them. The spirit of the thing is growing around the Harvester plant at Hamilton, and it does not take much imagination to see where the Council plant is going to grow into a good sized tree, well worth the space it occupies in the organization, and fully justifying all the watering, pruning and enriching it has received.

Real Suggestion Brought Out

But what is there of real help in the meetings of the Council. You must remember that the company pays the men for the time they spend attending these sessions, pays expenses if they find it necessary to make a trip, pays for the time matters are being discussed outside of the Council chamber. What comes in return? Well, a casting came back from away out in the west one day. It was broken, and the matter came before the Industrial Council. It wasn't simply replaced and the broken one put on the scrap heap at the foundry. The men responsible for the making of these parts had a chance to talk the thing over. One man believed that there might have been

Sports of all sorts are encouraged by the Harvester council, and here is seen one of the ladder stunts, in which a record was made that still stands.

some trouble in loading explaining how it could be done to avoid undue packing stress. Another was of the opinion that from the nature of the work, it should have been made from malleable in the first place, and gave reasons for stating that. Another had a suggestion to make about the design which might lend added strength to the part. Every suggestion that was made was practical, and worth money to the firm. Could all these suggestions have been secured and recorded in any other way? Not that we know of in so short a time and under such practical circumstances.

Again, the committee that has charge of health, safety and kindred work around the plant, bring in their report. Do they deal in glaring generalities, or do they have something real to talk about. Judge for yourself from this:

These recommendations were made to the superintendent, and the report given carries with it the action that has been taken:

The crane in malleable foundry be repaired, thoroughly overhauled, and put in good running order as soon as possible.—Ordered done and nearly completed.

Concrete floor in malleable sorting room be repaired. —Ordered done and completed.

Platform outside of malleable foundry be repaired.—Ordered done and completed.

Installation of air hoist over tumbling barrels in malleable foundry be completed.—Ordered and being done.

Hole in platform at dock be repaired.—Ordered and done.

Exhauster hoods for emery grinders in forge be pushed along.—Being moulded.

Crane for die rack in press room be completed and installed.—Ordered and drawings being prepared.

All telephone transmitters be cleaned and disinfected. —Ordered done.

Those instances are given to show that the men themselves, under this plan, are largely responsible for the conditions under which they work, and if there is anything that is not right, or that makes it an undesirable place in which to work, the remedy is in their own hands. There is nothing academic about the discussions. They are real and pertinent. If good they are acted upon, if not, they are considered and passed up.

How the Shop is Divided

The workings of the plan for selecting the members of the Industrial Council are similar to those published previously in this paper. The method of dividing up a shop for the purpose of giving proportional representation to each department is interesting. In the Harvester plant it is divided as follows:

Division 1.—Cold Drawn, Iron House, Steamfitters, Press Room, Forge Shop, Bolt and Nut.—277.

Division 2.—Grey Iron Foundry, Grey Iron Mill, Grey Iron Core.—284.

Division 3.—Malleable Foundry, Malleable Mill and Anneal, Malleable Core.—254.

Division 4.—Metal Pattern, Wood Pattern, Malleable Finish, Tool, Machine Repair, Fire and Watch, Electrical, Engineers, Experimental, Planning, Drafting.—273.

Division 5.—Wood, Canvas, Lumber, Traffic, Truck and Storage.—263.

Division 6.—Box, Erecting No. 1, Mower, Machine, Sheet Metal.—267.

Division 7.—Shipping, Packing, Repairs, Stock Room, Office, Production, Cafeteria, Yard.—251.

World Wireless Service

An extensive wireless service is contemplated between the French Colonies and the Mother Country. The scheme, according to Wireless World, is divided into four sections. The first section, which aims at providing communication between ships at sea and coastal stations, is already working satisfactorily, but further extensions will be made. The second section will be used to maintain regular communication with the mountainous regions, which, owing to the weight of snow invariably bringing down wires, are out of communication during the winter. The coastal system will ensure communication between France and islands round the coast; it is hoped also to link up Algiers with Paris. The third, or Franco-European system, is already started, wireless communication having been established since May with Hungary, and it is hoped shortly to open up communication with Belgrade also. The fourth section covers the linking up of the French Colonies, including Saigon, Noumea and Tahiti, with France. Stations with a transmitting range of 7,500 miles will be erected at Paris, Saigon and Tahiti. Less powerful stations of about 4,300 miles range will be constructed at Jiboutil, Antananarivo, Noumean and Martinique. Smaller stations will link up the French Possessions in Africa, connecting Martinique with French Guinea and Saigon with Pondicherry. The Ministry of War has already begun the construction of stations in the French Congo, Anatanarivo and Saigon.

THE LOOK-UP MAN

If you are away from sickness or any other cause, they don't just wait for you to come back. The look-up man is sure to call and see what's wrong and how you are being attended to.

The hospital at the Harvester plant is in a separate building and the services of a doctor and nurse are always available. Through the efforts of the council, accidents are being reduced in the plant.

MANUFACTURE OF WIRE ROPE

By J. H. Rodgers

THE first requisite in the manufacture of wire rope is the selection and blending of the different iron ores. The different processes through which the metal passes, and the hammering and drawing into rods require great experience, and give to it peculiar properties that are essential for the finished product. The story to follow tells how the Anglo-Canadian Wire Rope Co., Limited, Rockfield, Que., manufacture their line of rope, this varying from the smallest wire rope up to cables 1¾-inch diameter.

The care necessary regarding the selection and blending of the iron ores is equally needed in the annealing and hardening processes, during which the wires are drawn through dies to the required gauge. It is very important that the operation of drawing be performed at a uniform speed through the entire length of a hank of wire, otherwise there is a great possibility that the strength of the wire will vary at different points. After drawing the wire that is used for certain duties is subjected to special processes of galvanizing in order to make it proof against atmospheric and other influences. Experiments have shown that when the first wire in a rope breaks, it may be assumed that the rope has passed through one-half of its life, and as no one knowingly works a rope until it breaks entirely, then the breakage of a few wires is a sign that a rope should be carefully watched and replaced by a new one at the earliest opportunity.

Various Types of Ropes

The flexibility of a wire rope depends upon the number of wires of which it is formed; consequently the use to which a rope is to be put will partly determine the number of wires used in its construction. In some cases nearly 400 individual wires are employed in making one rope. Fig. 1B shows in section some of the types of construction, the particulars of which are as follows:—

1.—Laid rope of 6 strands of 7 wires each. This is the class of rope most frequently used for hauling ropes, where the size of the drum and sheaves will permit; it is also the make of rope in general use for standing rigging, and is such as is required by Lloyd's regulations.

2.—Hauling rope made of 6 strands, each being of 7 wires covering 7 smaller ones.

3.—Hauling rope made of 6 strands, each strand made of 8 wires covering 7 smaller ones.

4.—Hauling rope made of 6 strands, each strand made of 10 wires covering 7 smaller ones.

5.—Formed rope made of 6 strands of 19 wires each. In larger sizes this make of rope is used for standing rigging on vessels. In smaller sizes it is sometimes used for running rigging, and it is the usual make of rope for travel warps.

6.—Flexible steel rope made of 6 strands each of 12 wires with hemp heart and hemp centre in each strand. This is the usual make of flexible steel wire rope 4½ inches in circumference and smaller, used for hawsers, running lifts, hoists, etc.

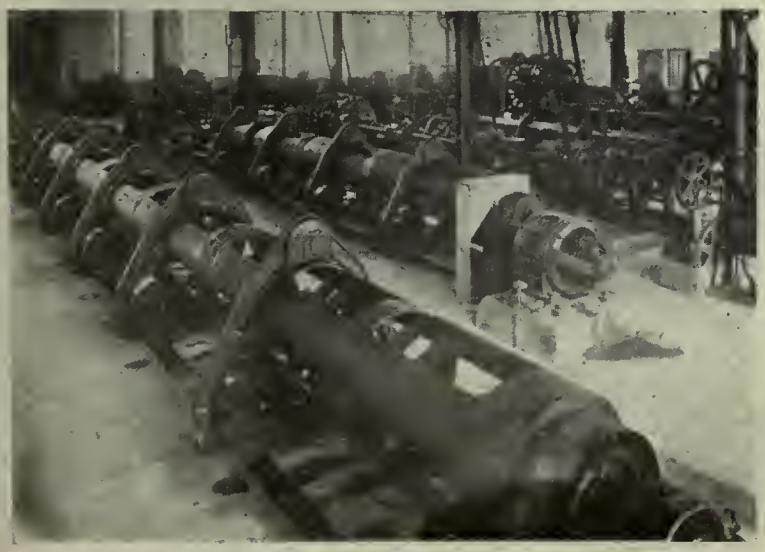

FIG. 1—GENERAL VIEW OF MACHINE SECTION.

FIG. 2—HIGH SPEED STRANDING MACHINE. DRAWING OFF GEARS IN FOREGROUND.

7.—Extra flexible steel wire rope made of 6 strands of 24 wires each.

8.—Special extra flexible steel wire rope made of 6 strands of 37 wires to the strand.

FIG. 3—SMALL TRIPLE STRANDING MACHINE.

9.—This is the make of rope usually adopted for large ropes—say over 10 inches in circumference—largely used for slipways and salvage purposes.

Testing the Wire

At the plant of the Anglo-Canadian Wire Rope Co. every bale of wire is subjected to rigid test before it is allowed to be worked up into rope. Before the wire is reeled on to the bobbins a short piece is cut from each hank and given a physical test to determine its torsional and tensile strength. The test for torsion or twist is made in a small hand machine similar to that shown in Fig. 1A. The bed of this machine (which is located on a bench) is graduated into inches, so that the length of the section of wire under test will be indicated by the setting of the front end of the tailstock A. The spindle of the tailstock is so fitted that it will not revolve, but has a short endwise movement to accommodate the shortening of the wire when twisting. The two springs B are provided to keep the spindle in the extreme open position. The hollow shaft allows the wire to be run through from the rear so that it may be secured in the two chucks C and D. The fixed headstock E is fitted with a revolving spindle, operated by gearing F and the crank G. To the middle of the spindle the worm H is secured, which meshes with the worm-wheel I, fastened to the vertical shaft that carries the indicating dial J, each graduation representing one turn of the spindle and likewise the wire.

Making Strands on "Snake" Machine

Fig. 1 shows a general view of the machine section of the plant, with two "snake" stranding machines in the foreground. These two stranders working conjointly are capable of turning out the standard 19 wire strands at the approximate speed of 300 feet per minute, the barrel of the machine having a maximum speed of 500 revolutions per minute. Every machine is operated by individual motor drive and the controller is located at the drawing off end of the machine where the operator stands. Fig. 2 shows the finishing end of one of the "snake" machines, with the gearing that is necessary for drawing off the completed strand. The speed with which the strand is pulled through the dies, in relation to the speed at which the machine is revolving, determines the length of lay. This factor of lay, or helix, is the fundamental essential in successful rope making. This is especially true when strands are composed of more than seven wires. It is very important that "crossing" of the wires in a strand be avoided, as this will cause excessive stress and eventually result in a weakened or broken wire.

The "snake" machines are of the most modern type for making the strands, as they are capable of being operated at high speeds, accelerate rapidly, and are quickly stopped when the occasion arises; suitable braking facilities being provided and always under the control of the operator when standing in a working position. These machines have no central shaft, the revolving section being in the form of a hollow drum, open at intervals to permit of inserting and removing the bobbins, and threading the wires through the various rollers to the forward end, where they all converge toward the centre wire, around which they are twisted and thence pulled through the die by the action of the drawing-off gear. The revolving portion of these machines is made of cast iron, and built up in sections, rigidly secured together to form one continuous hollow drum. Within this drum, and uniformly located, are the suspended cradles which support the bobbins.

The wire from the bobbins is passed through a number of small pulleys or rollers supported in brackets secured to the inner surface of the drum. Plenty of space is allowed in the groove of these rollers so that the movement of the drum permits the wire to swing about the centre, but without any perceptible twist until it reaches the front head. Each bobbbin is controlled by a brake which acts as a tensioning device, so that equal strain can be applied to each, allowing the wires to unwind uniformly. If the tension is insufficient there is a possibility of the wire buckling, and if too great there is danger of the wire breaking.

While the run of wire is generally of such a character as to permit of uninterrupted operations for long periods, it sometimes happens that a wire will break when the strand is being made. This necessitates immediate stopping of the machine. If the wire breaks before the twist is made, it simply means that the ends are prepared and placed in a small portable electric welding machine and joined together, and afterwards ground to eliminate any irregularities on the surface. This does not appreciably affect the strength of the rope. The tension is again adjusted on the bobbin and work is continued.

The drawing off is performed by passing the finished strand around a large pulley, the circumference of which is of a specific length. The shaft that carries this pulley is provided with a worm that drives a worm gear and

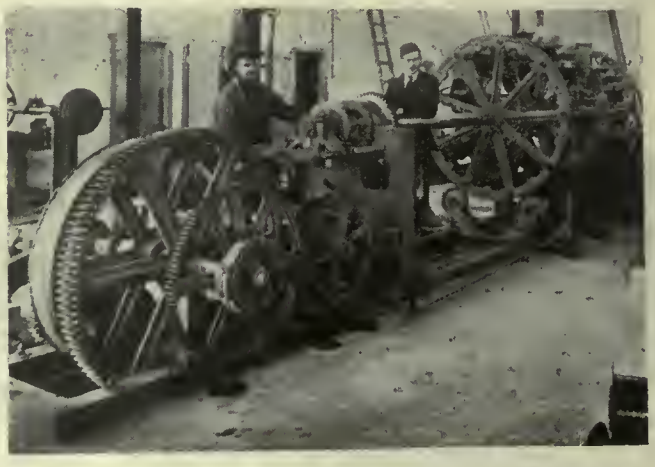

FIG. 4—EIGHTEEN BOBBIN SECTION OF LARGE TRIPLE MACHINE.

vertical shaft, to which, at the upper end, a graduated dial is secured. This dial indicates the number of feet of strand that has been drawn off. After making several turns of the winding wheel the strand is reeled on to the bobbins. These are likewise power driven, geared in unison with the winding equipment. The bobbin shaft,

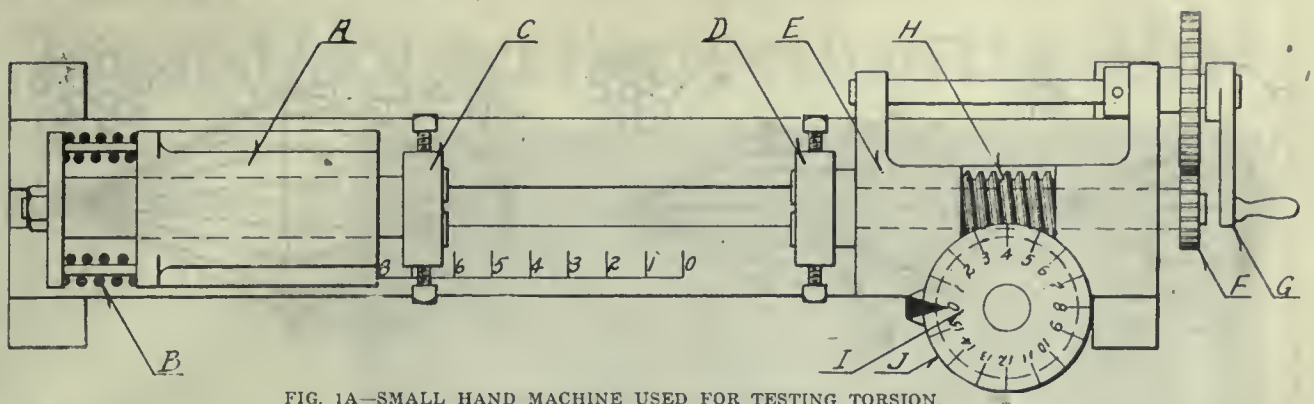

FIG. 1A—SMALL HAND MACHINE USED FOR TESTING TORSION.

however, is driven by means of a friction clutch, to provide for the varying diameters as the wire on the bobbin is increased in volume. Oscillating forks are fitted on the lead side to assure a uniform tracking of the strand. When strands of 19 wires are being made on these machines, the inner section of six wires over one is made on the seven bobbin machine, and this strand is covered by 12 wires in the twelve bobbin machine.

FIG. 5—BOBBIN CONTROL MECHANISM ON CLOSING MACHINE.

Making Combination Strands

A small triple stranding machine is illustrated in Fig. 3. This machine is capable of making strands of every construction for ropes up to 3-4-inch in diameter. The complete strand can be made in these machines at one operation, each head taking care of one gallery of the strand. To roughly show the various details in the making of a strand of 37 wires, the sketch Fig. 3A is given. This is a skeleton diagram of a triple machine, the small head at the lead end taking care of the first section (2) of seven wires (which may, if desired, be used as a strand itself); the second head winds twelve wires about the first seven, giving a strand as shown at (3). The third and last gallery of eighteen wires is wound on by the third or largest head, the result being a strand of 37 wires as shown at (4). It will be noted that the wires here shown are relatively much larger than the machine parts shown, but the purpose of the sketch is to illustrate the general arrangement of the wires as they are located in the different heads, and the process of construction from the single wire to the completed strand.

It should likewise be noted that the centre shaft (which carries the wheels G, for supporting the bobbin cradles and shafts) is not included in the drawing. It should be understood that the central shaft in each head is of the hollow type for the free passage of the largest wire or strand passing through. It may also be stated that one or more heads may be disconnected, or operated in opposite directions, so as to obtain any desired strand construction.

In these triple machines the bobbin that carries the centre or core wire (1) is placed on a reel apart from the machine proper and drawn through the central shaft by means of the drawing off gear. The six bobbins D, for the first gallery (2), are located in the primary head, the bobbins being kept in a vertical position by the action of the eccentric ring A and cranks B, one of these cranks being fitted to the end of each bobbin shaft. This detail will be explained later. The forward bearing of the bobbin cradles is hollow to permit the passage of the wire. After passing through these holes, the wires converge towards the centre and pass through the lay plate F, the combined forward movement of the wires, and the revolving motion of the heads, giving the proper lay de-

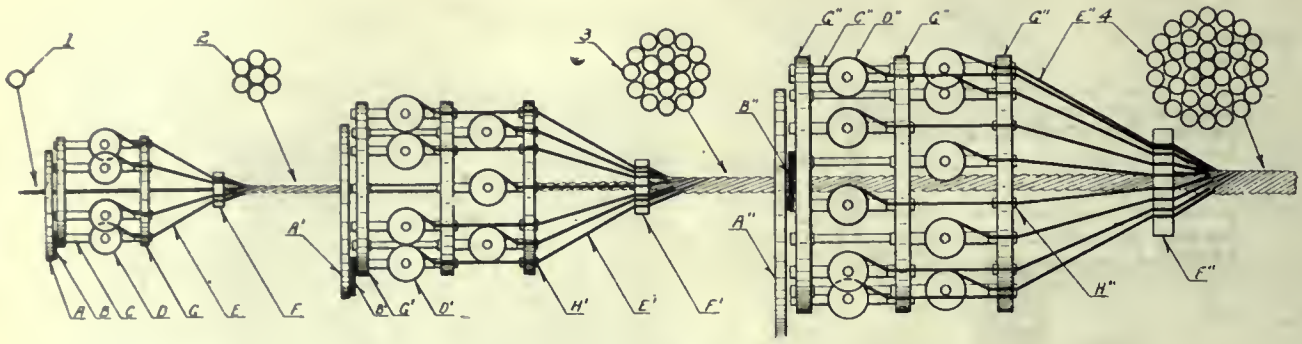

FIG. 3A.—SKELETON DIAGRAM OF TRIPLE MACHINE.

sired for that particular strand. Immediately after the twisting operation, the strand, or that specific section of the strand, is drawn through a die that assists in equalizing the lay of the wires. The different heads, with the exception of the varying size, are quite similar; the larger ones have the bobbins divided into two sections to enable the required number of bobbins to be located in the frame without interference. In this case, the wires from the rear division extend across the forward space and through a bush inserted in the forward containing ring G. The bobbin shafts C on the double heads extend back to the rear ring for connecting up with the eccentric ring A. An eighteen bobbin section of a large triple stranding machine is shown in Fig. 4. This machine has a capacity for making strands of 37 wires of any construction for rope from 1-2-inch to 1 3-4-inches in diameter, in one operation. The machine complete weighs about 21 tons.

Making the Rope

The title cut illustrates the closing machine used for the last operation in the manufacture of wire rope. This particular machine has a capacity for rope up to 1 3-4-ins. in diameter. With the possible exception of cables required for special duty, every wire rope is constructed with a hemp heart, around which the six built up strands are located. This hemp rope is passed through the hollow shaft of the machine in much the same way as the core wire on the triple strander. Before passing to the machine, however, the rope is drawn through a small tank of special lubricating grease which is kept warm by means of an electric heater. The bobbins containing the strands are mounted the same as in the triple stranding machines, and, as a matter of fact, the different machines in a wire rope plant vary only in detail and not in principle.

A detail view of the bobbin control is shown in Fig. 5 and a line sketch of this mechanism is illustrated in the line sketch Fig. 5A. The general design, which is typical of all machines, calls for the use of a separate ring to control the movement of the bobbin shafts. It is essential that premature twist be avoided when closing the rope, and therefore it is imperative that the bobbins be kept in a vertical position while they revolve about the axis of the machine. The central shaft A is supported at either end of the bobbin frame, but owing to the construction it is impossible to provide intermediate bearings; adequate support is provided by running the large wheels B on the rollers C, one of these being located at either side of the machine and secured to the base plate D. The roller brackets are adjustable for centre distance by means of the tie rod E. The bobbins F are carried in cradles G, which in turn are supported in the containing wheels B. The shafts of the forward cradles extend back to the rear for crank connection. These cranks are keyed to the respective shafts so that the cradle bearings for the bobbins are horizontal when the cranks are vertical. The cranks K are all of the same centre distance and when connected to the eccentric control ring H, bring the centre of the latter a like distance below the axis of the machine. This ring H is free to revolve about its own centre and is kept in vertical alignment by means of the two guide rollers I, which are located on studs passing through a cross bar J of the machine frame. It is quite obvious that, no matter in what position the machine may be, the cranks, and likewise the bobbins, will always be vertical.

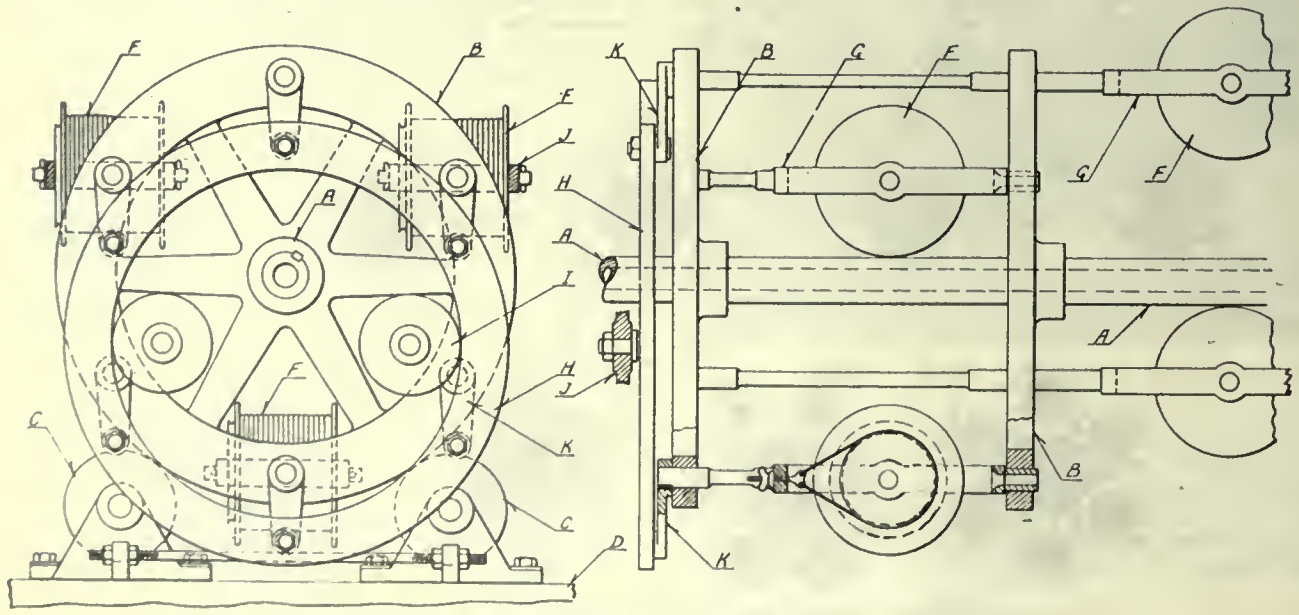

FIG. 5A—DETAILS OF MECHANISM OF BOBBIN CONTROL.

Treat *Machines* Better than the *Men*?

Well, Perhaps They Didn't Mean It To Work Out That Way, But the Foundry of To-day Filled With Molding Machines is Brighter Than the Old One Filled With Men

By F. H. BELL
Editor "Canadian Foundryman"

A TYPICAL MODERN FOUNDRY BUILDING. ABUNDANCE OF LIGHT, HEAT AND VENTILATION.

COULD there be anything more interesting or fascinating than the moulding and founding of metal? To see the agile artisan plying his tiny tools and his dexterous fingers in the skilful preparation of the moulds, and to see this same artisan and his nimble fingers converted as though by magic into a giant of herculean strength with brawny arms conveying the ponderous ladles of molten metal, boiling and seething from the melting furnace, to be poured into the moulds which he had just completed a few short moments before? To see the honest sweat streaming from his brow as he tears the moulds asunder, and exposes to view the red hot castings, true to every detail, and to note his beaming countenance as he gazes with well-deserved pride upon his handiwork?

Truly, it is a magnificent sight.

Yes, the programme of the moulder is wonderful, but for those of us who have spent our days within the gloomy precincts of the moulding shop as a means of keeping soul and body together, much of the grandeur and magnificence has been overlooked, or perhaps the fascination and the interesting features in connection with the moulders' noble art did not present themselves to us with the same degree of prominence as did some of the other more notable characteristics of this most necessary institution—the foundation of all mechanical achievements—the foundry.

The Surroundings Were Dingy

But they were there just the same, hidden away behind a sand heap or buried beneath a pile of debris, and while our eyes were bleared with core smoke and our brains befogged with foul gas and dust, we allowed the fascination of the surroundings to go unnoticed.

It is all right for the uninitiated foundryman who has received his foundry experience at the office desk to say that we take the wrong attitude, which perhaps we do, but under conditions as they existed there was no other attitude which a person could take.

But with all its shortcomings, the foundry, with its various features, is one of the most interesting of callings and one which bids fair to hold a more prominent place in the manufacturing world than it has done since the days of Tubal Cain.

Improvements Have Come

If the moulder, who perforce sees nothing but the dismal features, cannot become interested enough to suggest improvements, it behooves the employer to do so, but up to a comparatively recent date moulders have been so plentiful and apprentices so eager that no thought of change was ever considered, and if Tubal Cain could have come back to earth forty years ago and could have visited the average foundry he would have identified most of the equipment as his invention and would no doubt have been able to point out improvements which he had devised and which had since been forgotten.

With modern improvements in other lines of occupation and with increased educational advantages, the youth of the last few decades has not taken kindly to foundry work, with the result that moulders were becoming extinct and the trade a lost art. With the shortage of workmen came the idea of replacing them with machines, but little attempt was made to improve the conditions so that machine operatives could be retained and as a result common laborers drew the line at machine operating amid such surroundings as were met with in the foundry. This resulted in the employment of foreigners who, so far, have done most of the machine moulding in this country.

Must House the Machine

But now comes the difficulty which touches the tender spots. It has been discovered that the foundry is no place in which to install a machine, or in other words, it does not pay to keep a foundry in such a condition if machines are to be used. It has been found that no matter what precautions have been taken by the manufacturers of foundry equipment, the dust and dirt of the foundry is too much for a machine to endure, notwithstanding the fact

that human beings were expected to endure it through all the hundreds of years since foundry work began.

As a result of this latest discovery, an organization has been started which embraces practically all the manufacturers of foundry equipment and is known as the Foundry Equipment Manufacturers' Association. They have begun a determined campaign to induce foundrymen to make their foundries fit places for the equipment, and this campaign is already having its effect and to-day no foundryman would think of building a foundry without engaging an industrial engineer to design and superintend its construction. The result of this move has been most satisfactory and now we may look forward to a new era in foundry work. Like war, which with all its horrors, brings out inventions which would probably never have been thought of in the ordinary course of events, so the foundryman, with his careless indifference, has been the means of bringing out improvements which would not have been considered necessary had it been possible to continue in the old way.

Some Practices Contrasted

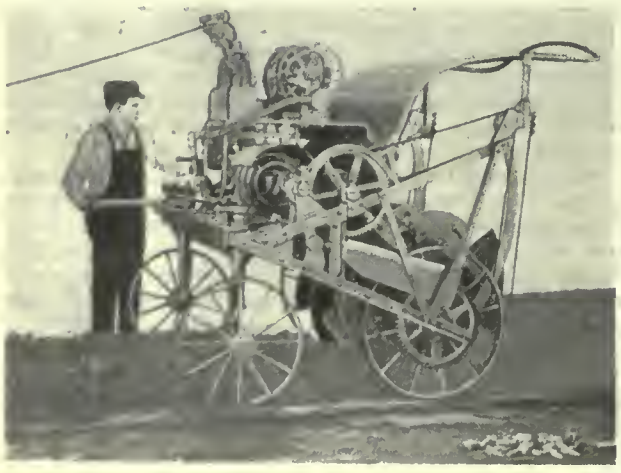
As a comparison between the methods of my boyhood and those of to-day, I will give a few examples which should convince the reader that the foundry is no longer lagging behind. In those days the apprentice was put through the entire foundry process, which included attending to cupola. This part did not appeal to him, but it was the proper thing to do and should still be the rule. He cleaned castings, helped cut over all the sand heaps in the shop, made cores, etc.

To begin with, the castings had to be removed from the sand by hand. To-day they are placed upon the table, suspended from the trolley car.

Then the water was thrown on from a pail—now it is put on with the sprinkling system.

After being wet down two men took opposite sides and with shovels smashed the lumps and cut the sand up in a heap. Now the sand-cutting machine straddles over the floor and in moving the length of the room leaves a finished sand heap in its wake.

In the core room the sand was prepared by getting a barrow load of sharp sand, a pail full of moulding sand and a measure full of flour. These were all pitched back and forward until considered mixed, after which the mass was run through a No. 8 sieve. It was then spread out



THE MODERN METHOD OF CUTTING UP THE SAND HEAP.

and punched full of holes with the shovel, and wet down in a similar manner to the sand heap and cut over several times to be sure it was mixed, when it would this time be run through a No. 4 riddle. Now the sand is mixed and tempered in a power-driven sand mixer.

Formerly the cores for every purpose were made in halves so that there would be a flat surface against the core plate. The halves would be dried and afterwards pasted together and dried again and black washed. Now, cores are jolted into the core boxes, or blown in by compressed air, and for straight round cores or even cores which are not round, a machine similar in many respects to a sausage stuffer is used and the core made perfectly

THE REGULAR WAY OF POURING COMPARED WITH THE METHOD WHICH IS COMING INTO VOGUE.

true, of any length required and with the vent hole the entire length.

More Laborious Work

In charging the cupola the only means of getting the coke and iron on to the platform was to carry it up the stairs and dump it on the floor, after which it was rehandled and put in the cupola. The cleaning away from under the cupola was equally as interesting. The coke, iron, cinders and sand had to be separated by hand, by picking out the coke and putting it in a basket. Bits of iron were put in a tote box and the cinders which did not appear to carry much iron were wheeled to the dump. The balance was put in the cinder mill along with the siftings from the sand, and from the gang-way a few chunks of pig iron put in with them, and the whole outfit tumbled until nothing was left but the iron. The cinder mill was, of course, well supplied with openings to allow the ground cinders to escape and that which was not heavy enough to fall to the floor did the next best and went all over the shop in the form of dust.

But It Is Different Now

To-day there is no part of the plant better taken care of than the cupola. Wet cinder mills grind up the cinders and separate the coke and iron and are dustless. Sand sifters of various types are provided for sifting the sand which will form the bottom, while magnetic separators recover the last speck of iron from the gangway and hoists to suit every condition are used to deliver the material to the charging floor.

The scratch room of to-day instead of being the dust-laden department of former days is as free from dust as any part of the plant. Instead of putting the castings in the old-fashioned tumbling mills, similar to the one back of the cupola, the tumbling is done in tight mills which are connected to exhaust fans which carry all the dust outside of the building. The grinding wheels are likewise connected to the same system. In addition to these there are new devices which were not known many years ago and which are not only labor-savers, but are reasonably dust-proof. Instead of the hand scratch brush and the

chisel and hammer, the modern foundry is equipped with revolving scratch brushes which are either operated on a machine similar to the grinding machine or carried about on a flexible shaft or on a portable grinding apparatus. Pneumatic chisels and sand blast apparatus of innumerable types do the work cheaper, better and healthier than formerly was the case.

The Modern Way of Pouring

But the part which is of vital interest to the employer and employee alike is the progress which has been made in methods of making and pouring the moulds. Up to a very recent date this was done entirely by hand and the moulder had to keep up a continuous motion every minute in the day or else he did not do a full day's work. To-day machinery does the bulk of it and the moulder's part is not the slavish job it used to be. As we have shown, the sand heap is prepared by machinery and no matter what class of mould is to be made there is a machine which can be used to advantage on it. In pit work the grab bucket cleans the pit out and the automatic sand sifter riddles the sand; the sand mixer prepares the facing sand; the pneumatic rammer does the ramming and the power crane does the lifting. In doing floor work the jolter does the ramming and if the work is such as will warrant the outlay, the jolting machine is built to turn the mould over. If the work is large the electric crane is used for lifting, but for medium work the pneumatic hoist is used to exceptionally good advantage and in many places the differential pulley block such as is built now can be used where no other device is as satisfactory. For small work such as has been considered as bench moulding, the squeezer has been perfected to such an extent that it will do most any job which was formerly done on the bench, and for work of a more difficult class the jolter, squeezer, stripper and pattern drawer offer a sufficient variety from which to choose the required combination to do practically any job.

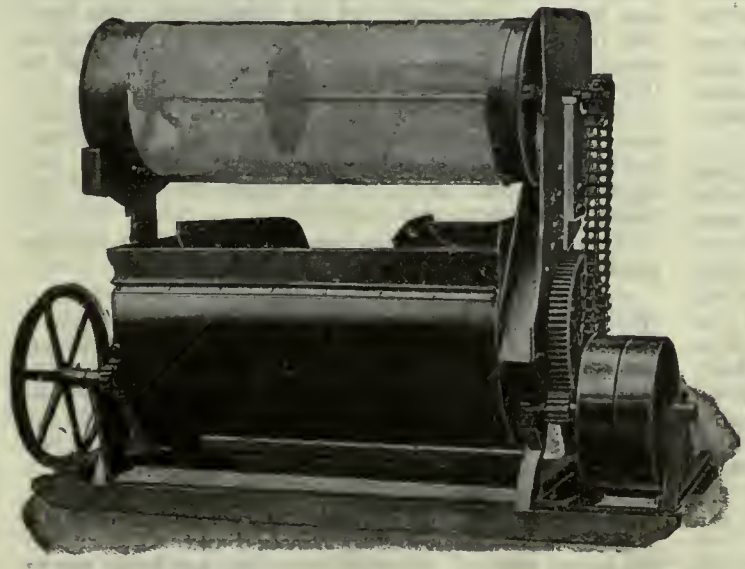
Oven for the Job Shop

For jobbing work where the pattern-drawing device cannot be used to advantage the air hoist has many advantages. The air hoist is also used advantageously for lifting copes, handling cores, etc. For heavy lifting, cranes have been used for many years, but they were hand-operated. To-day almost any foundry will have electric cranes traveling the entire length of the shop and in addition have numerous small pneumatic cranes which can be lifted from place to place by the electric crane and connected to the compressed air pipe by means of a hose. In addition to this a modern foundry is equipped with trolley track connecting the cupola spout with the different floors, so that the moulder has no carrying of metal excepting on his floor and this is being dispensed with now to a considerable extent by the use of pouring systems which connect up with the main track. These pouring devices are so perfected that the ladle can be raised to any height and the mould poured to as good advantage as could be done by hand and with greater ease.

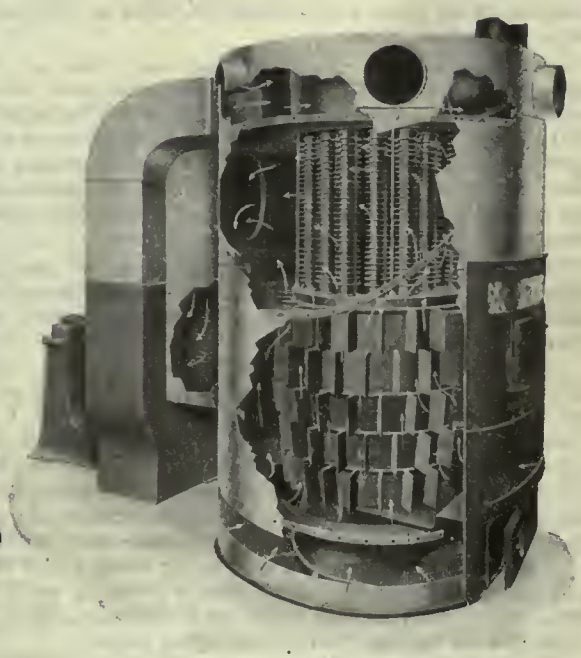
All told, the foundry of to-day is on a par with any other business, with the possible exception of the atmospheric conditions and these as we have already pointed out are being rapidly brought into line in order that the equipment will give the maximum of efficiency and the men who had been overlooked are automatically absorbing the benefits which were primarily intended for the machines.

By employing competent industrial engineers who have had actual experience in the foundry to superintend the construction as well as the heating and ventilating of the new foundries, it has been found quite possible to have good, clean air which does not stick to the oil on the machinery and which does not stick in the lungs and nostrils of the workmen.

CUTS CORES TO EXACT LENGTH AND TAPERS THE END.



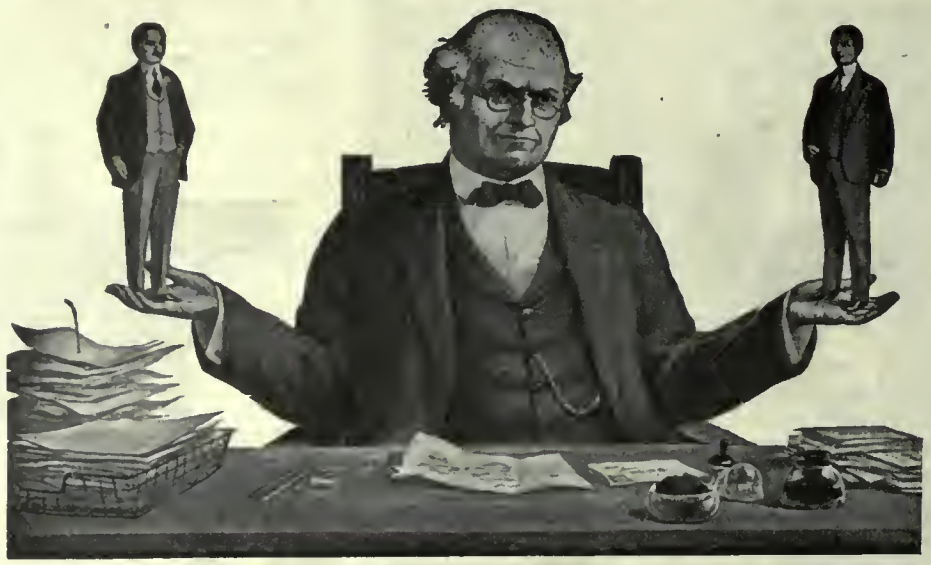
SIFTS THE FACING OR CORE SAND AND MIXES IT IN ONE OPERATION



HEATS AND VENTILATES THE FOUNDRY AT THE SAME TIME.

Every Man Cannot be an Executive

Some men prefer their regular shop work to any style of office position. This tale, while fanciful, illustrates that dissatisfaction is, after all, largely imaginary.



"WHEN are you coming home, Jack?" My wife was phoning me at the office, and in my tired condition, her voice sounded as if it were a thousand miles away.

"I'm sorry," I replied, " but I will be at least a few hours yet. I have some important appointments, and it may be ten or eleven o'clock before I get through. Eat your supper alone. I'll be home as soon as possible."

"I'll bet you're tired," came back my wife's voice. "You win," I replied, wearily, hanging up the phone.

Reviewing the situation, I could not help feeling both disappointed and disgusted. Here was I, working till all hours of the night in an endeavor to pacify, and perhaps satisfy, a plant filled to the door, so to speak, with disgruntled workers. Truly the position of manager in a manufacturing plant was no sinecure, much as some would have you believe it so.

For the past few months things had gone far from smoothly. Threats of strikes had been numerous, and the cry had always been the same. "MORE MONEY, THAT IS WHAT WE WANT." Never had there been a word about production. In fact, had I stated that production had gone down instead of up, the workers would have keenly resented my critical attitude, and perhaps have struck, just to show they were of an independent nature.

And yet, had I not the right to speak on that very point? viz., that if wages go up, production should soar accordingly. Suppose, I pointed out, that profits were lower—but there again was a nasty snag.

Profits—why the workers hated the very word. They felt that the firm was making millions, when truth to tell we were just working on a safe margin. True, I was making a comfortable salary, but why shouldn't I? Was I not working for it just the same as the men in the shop? To the men in the factory, I was the fellow who held down the soft snap, who wore a clean collar and a silk shirt every day, and rolled down in my limousine around 11 a.m.

The truth of the matter is, I never wear a silk shirt, and can afford nothing larger than a Ford. I am at the office every morning not later than 8.30 a.m., but you know the old saying, "Give a dog a bad name."

In thinking these things over, I must have dozed off, for suddenly I awoke to find a tall dignified stranger confronting me.

"Pardon me," I said, "but I don't seem to know you."

"You do—and you don't," said the unexepected visitor." "You used to know me, but lately you've neglected me terribly."

His manner of speech puzzled me and I must have looked it, for he continued, "If agreeable to you, I want to help you out of your present quandary. Don't bother explaining, for I know all about your trouble. You wonder who I am, and how I know of it? Well,—my name is Courage. all men need me but seldom use me. Lately, they have been using my brother, who is known as Let-well-enough-alone. Candidly, if you don't mind my saying so, that is your trouble so far."

I was taken aback and must have looked it. Finally I stammered, "Well, what to your mind is the solution to the present trouble?" My visitor seemingly paid no attention to my last remark for he replied, "Why did you stay at the office to-night?—don't bother answering, for I know already. You have made engagements with various men in your plant who are dissatisfied. You have also arranged for them to come at different times, a rather clever idea in its way,—but why are you meeting them in this secret manner? I'll tell you."

The method of my visitor's asking, and answering his own questions was rather disconcerting, but wait, he was continuing: "You expect, by meeting your men one by one to pacify them, thus avoiding the latest of the threatened strikes. Am I right?"

I had to admit he was, but ventured to ask how he guessed.

"I never guess, I know," came back the dignified reply. "Look here, Jack (why, he even knew my first name), you've got to do something definite, or a strike is assured. Why not take me as a side partner? I want no wages or profits, and my cousin Good Judgment will come at the same figure as myself, namely, consideration. Between the three of us we can see this matter through. What do you say?" I nodded my head, and the moment I did so, in walked Good Judgment.

He recognized me as an old friend and the three of us bent our heads closely together, discussing the situation to our hearts' content. We laid a plan, that had better not be

told for the present. Enough to say that it was none too soon, for there was a sudden knock on the door, telling me that the first of my expected visitors had arrived.

"I don't want these men to see you," I said to my two companions.

"They won't," replied Courage laughingly. To them we are invisible. To you, we are ever present, but remember this, we are of no use to you except you use us. You must ask us to help. Good Judgment will help you out of many a hole, and personally I'll give you the courage to see it through, but remember, you, and you alone, can command us.

With these warnings ringing in my ear, I shouted "Come in," and the door opened to admit Waeburn, the head of my automatic department.

The Plan Works

Waeburn seemed ill at ease. "What is it you want?" he commenced. I felt Courage right beside me so started in with my heavy artillery.

"Look here," I replied, "you asked me to-day for an increase of $600 per year, and threatened to call your men out, if you didn't get what you asked. Why?"

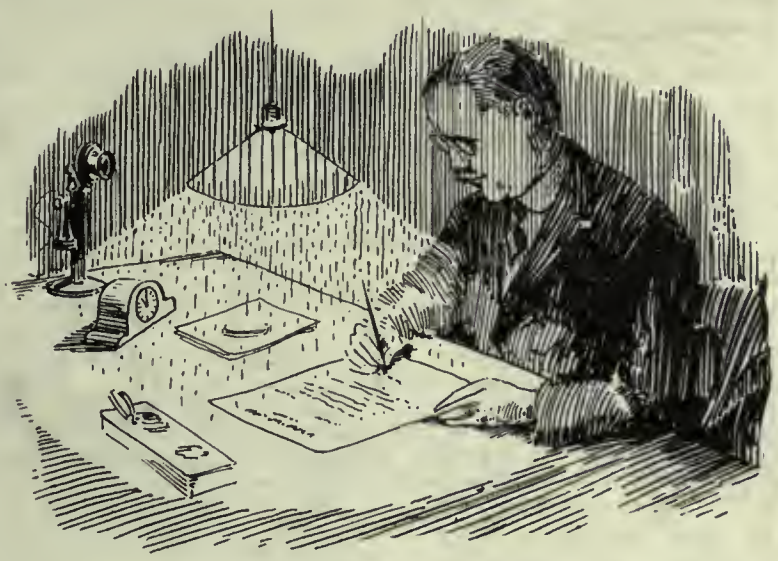
This certainly was not the sort of conversation I had intended having at the start, but Good Judgment whispered in my ear that it was for the best, so I kept on that track.

"Well," replied Waeburn, "I want more money because I've recently got married and I find the going rather rough."

"Is that the only reason I should give you $600 more every year?" I asked.

"No," came back Waeburn, "but I've done my work for the past five years as best I know how."

"That is your opinion," I shot back.



My workers imagined that I wore a silk shirt, and rolled down in my limousine about 11 o'clock every morning. Instead of that I often work from 8.30 a.m. until 11 p.m.

This rapid fire reply staggered Waeburn, for he spluttered out that he didn't see why I should suggest he was not doing his duty.

"Look here," I continued, "let us talk this thing out in a candid manner. You listen to me first, hear my viewpoint, then see if you can still honestly ask for the extra $600. First of all, I admit you've worked for us for five years, two as foreman. In that time you have had a good chance to study your men, the machines, the operations performed on them and so on. In other words you should know your department pretty thoroughly by now."

"I do," he replied.

"Very well," I countered, "we will see if you do. Take operation XXX on that small spindle you are doing out in the shop at the present time; do you think we are doing that work in the best way possible?"

Waeburn looked amazed at me. "Why, we've done that job the same way for the past five years," he said.

"Sure," I replied, "that's the trouble. How do we know that's the best way. Have you ever tried any other method?"

The look on his face was answer enough, so I followed up my advantage. "Do you know that I had a young fellow up from your department to-day who suggested what looks like a better plan of doing that work? Of course I told him such a suggestion should come through you, but his reply was that he had tried to get your ear before, but his reception was far from pleasant."

"You mean young Smith, don't you?" sneered Waeburn.

"Exactly," I replied.

"Oh! he makes me sick, always some new idea. If he had his way we would reorganize the whole plant."

"Well, he's going to get his chance," I replied. "I'm placing him in charge of your department and starting to-morrow morning."

This statement was wholly unpremeditated on my part. I had never even thought of it before, but Good Judgment seemed to suggest it and Courage carried it through for me. Waeburn's face was a study.

"Where do I get off at?" he asked.

"You come into my position," I replied. You could have knocked him down with a feather. "Remember telling me yesterday I had a cinch of a job?" I asked. "You said you wished you could get such a position. You would show us what you would do. Well, you've got your chance now. I've been working too hard lately and I'm going to take a well earned rest."

"But look here," said Waeburn, hastily, "I was only fooling. I couldn't run your job. I don't know the first thing about financial matters and I don't know ———oh, what's the use, Mr. Blank, my place is in the shop."

"That's where you are mistaken," I replied, "but we will consider my first suggestion. In place of giving you full charge you'll work under my supervision. To start with, you get no more money than you are making at the present time, but if you make good, leave the salary matter to me and it will be very much in advance of the $600 you are asking for."

I looked at my watch, saw that my next visitor was about due, so decided to close the interview.

"Well, then, that's settled. Report to me at 8.30 in the morning," and I showed Waeburn out in a much more dazed condition than when he came in. In spite of the novelty of the move, I felt it was a good one, in fact Good Judgment told me it was and as for Courage, I felt quite proud of him.

The Second Visitor

Suddenly, in walked Grogan, my foundry foreman. It was like Grogan to walk in unannounced. He never knocked at my office door, and though I had often felt like telling him about it, I never had Courage with me before.

"Look here, Grogan," I said, Courage backing me up, "Before you come into my office knock at the door first, then wait to see if it is convenient for you to come in."

Grogan's face was a study. Never had he heard me speak like that. Somewhat abashed, he said: "Why, I never knocked before."

"All the more reason you should start now," I replied. With this remark, I considered that I had said enough and started on a new tack.

"You were raising Cain with me the other day," I commenced, "regarding the poor supplies you were getting for the foundry."

"You said something," he growled. "Why the purchasing department you have is a joke. There isn't a practical man in the lot. I could buy better than that bunch with my eyes shut."

"Do you think so?" I ventured.

"I'm sure of it," he replied.

"Very well, then, consider yourself purchasing agent starting to-morrow morning," I said, and Grogan's expression was something beyond description.

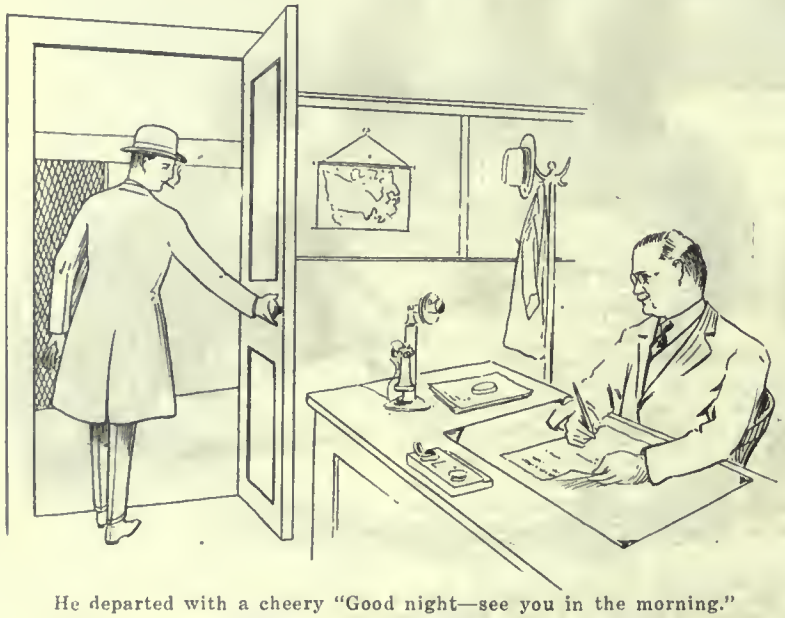
"Do you mean that?" he asked.

"Certainly," I answered.

"What about the foundry?" "Bell, your assistant, will run that," I replied. "Now look here. You've said a great deal about the need of a practical man in charge of the purchasing department. You've been with the firm since it started. As far as I know you started in the shipping department, did you not?"

A nod of the head was his only answer.

"Since then you have been through every department. From previous experience you should make an ideal man for the purchasing end of this business, so be prepared to dig in at 8.30 to-morrow morning. If you make good you get even more of an advance than you asked me for last week." With this remark I ushered him out in much the same condition as Waeburn, my previous visitor.



He departed with a cheery "Good night—see you in the morning."

An Easy One

The next visitor was easy to deal with. He was a new recruit in the drafting department, named Jones, who could see no reason why he should not be chief. As for the salary he was making,—well it was disgraceful, to use his own expression. In a previous talk with his chief I had decided to discharge this youngster, but on the chief's recommendation, I had agreed to let the matter slide. "There is good material there if we can develop it," said the chief. Personally I felt he would never discover it, as this fellow was one of the never satisfied type, but my rule is, give every man a chance to make good, so on he stayed.

The talk with him was brief and to the point. "You want to be chief, don't you?" I said. ,

"Yes," replied Jones.

"Very well, you are," I replied.

This remark took the wind out of his sails.

"You mean the present chief is discharged?"

"No, promoted," I answered. He is now chief engineer, but you are chief draftsman.

"What salary do I get out of this?" he asked. In a way I admired his nerve, but replied that his salary would remain as it was until he proved himself.

"In that case, I won't take the job."

This was a new one on me, and I had to call on Good Judgment for advice. "Take him up on it," was the advice given me, and I did.

"All right, how much do you want?" I said. With a smile at thus winning his point, the young upstart, if I can call him that, stated a figure equal to the salary of the regular chief. "You see," he explained, "I know what he gets."

I merely nodded, signified my acquiescence and told him to start in the morning. Somewhat cocky at my ready acceptance, he strutted out of the office with a "Good night, see you in the morning."

Courage smiled as he departed. "It took all my patience to go through with that," he said. "Instead of tolerating him, I felt like throwing him out." "Still," interrupted Good Judgment, "I believe it's best for the department. There are quite a few in that department who think they ought to be chief, and this will be a lesson to them." My next task was one of diplomacy. I called up the suddenly deposed chief, explained my scheme told him to let matters go only so far to the bad and wished him a cheery good-night. When all was said and done, I felt better than I had earlier in the evening.

This being my last visitor I closed the desk, and turning to my two friends, said:

"Where will I see you in the morning?" The reply was what I expected.

"We're going home with you," they replied, "and what's more, we're going to stick with you until the end, always providing of course, that you want us."

"I never needed two such friends as much as I need them now," I answered earnestly, and with that we all departed.

The Morning After

The morning following these sudden changes was a hummer. The men in the shop, who were thus suddenly promoted to be foremen of their various departments, had nothing on the three who were raised to positions of assistant manager, purchasing agent and chief draftsman respectively. I was on the job as usual to tell the new seekers after fame what they were expected to do. Rumors floated from department to department, and the one most generally conceded to be correct, was that I had suddenly gone crazy. Some of these wild guesses came to my ears, but I merely smiled, sat tight, kept right alongside of Courage and Good Judgment who told me to see all and say nothing.

The climax came when the following notice was placed on the bulletin board of every department throughout the plant: "Three men have lately been promoted to executive positions. This has been done with a definite purpose, viz., to help these men advance. If capable, they will be retained in their present capacity. The firm wish their men to be satisfied, and, if after three months, others desire an executive position, let them make their application to me personally."

If rumor was rife before, it was greater after the posting of this notice. The men could not understand it. Their dissatisfaction, which after all was only imaginary,

turned to wonderment. What on earth was the G. M. trying to put over them? Wonder changed to worry. Were the newly appointed executives capable of running the plant, and so it went on, until like all nine day wonders, interest waned and the shop went on very much as before.

Three Months Later

It was three months later that I had an uninvited visitor at my home. It was Waeburn, and a very changed Waeburn at that. After some humming and hawing, he blurted out the object of his visit.

"I'm a failure," he commenced, and then, out poured a tale of woe, that was already known to me through another source.

"I guess I'm not such a world-beater after all," continued Waeburn. "As an automatic department foreman I'm passable, but as assistant manager, well—I've made a mess of things, but thanks be I'm man enough to admit it. I've changed my mind a great deal since our last interview. Managing a firm is not all sunshine. I've tried hard. I've spent hours every night attempting to handle the job successfully, but I give up, it's no use, so, if agreeable to you, I'll leave a week from to-day."

"What seems to be your chief trouble," I asked.

"Frankly," replied Waeburn, "I realize now that one requires more than bluff to be come a manager. I fell down on the job simply because I lacked training, and in falling down, I also see why I was not satisfying you in my last position. As assistant manager I was entirely out of my field. Instead of liking the job, as I imagined I would, I much prefer work along my own line, namely, automatic machinery. I see plainly where I did not make the most of my opportunities in the shop. My policy was Leave-well-enough-alone, but I assure you, the lesson taught me has fallen on good soil. I tell you all this, to show that your giving me a chance to make good is appreciated. Having thought the matter over I decided to hand in my resignation."

"Where do you expect to go from me," I asked.

"I don't know," he replied.

"Would you consider taking over your old department?" At my question Waeburn stiffened. "Would that be fair to Smith, the present foreman?" he asked. I laughed. "Smith was in to me about an hour ago," I said, "and told me the job was too much for him. He is rather young yet and lacks experience, but Waeburn, you and he would make a great combination. What do you say? Will you accept?" It did not take him long to see my viewpoint, with the result that a notice was posted in the shop announcing his return the following week. On returning to the shop, he was honest enough to tell his men frankly why he had returned and that he had not made a success of the new position.

News of this character travels fast, and it was just a few days after Waeburn's return that I received a note from Jones, the recently appointed chief draftsman. His letter was written from his home explaining why he had not appeared at work the previous day. The note commenced in this strain:—

"When I took over the position of chief I was a hair-brained ass. Of course I didn't see it that way at the time, in fact I felt rather proud of myself, that at last I had convinced you of my worth. I felt it was a shame the way the firm had held me back. I was thoroughly convinced that my chief had a soft snap and that my knowledge was greater than his.

"Since taking over the position things have gone far from well. I pity my late chief when he once more takes over my position. I say this because, as far as I am concerned, I'm through. Unlike Waeburn, I'm not man enough to come and tell you personally, and I cannot go back to my old job again. By the time this letter reaches you I'll be on my way home. My folks often wanted me to go to college, but I like the crowd of goodfellows better. However, I've learned my lesson. I see that Education is the thing, and I'm going to get it. I intend taking a short College course for a year or two in the hope that by that time I will really be capable of holding a position such as you gave me an opportunity at. Where I fell down on the job was lack of experience. My theory was only half matured and my practical knowledge was nil. Incidentally, I intend to work in the summer months for some machine shop to build up on the practical end of the business. As I said before I've learned my lesson. From now on personal effort is what I will rely on."

I could not help but remember the chief's words as I read this letter. Truly the good in this fellow had come to the surface.

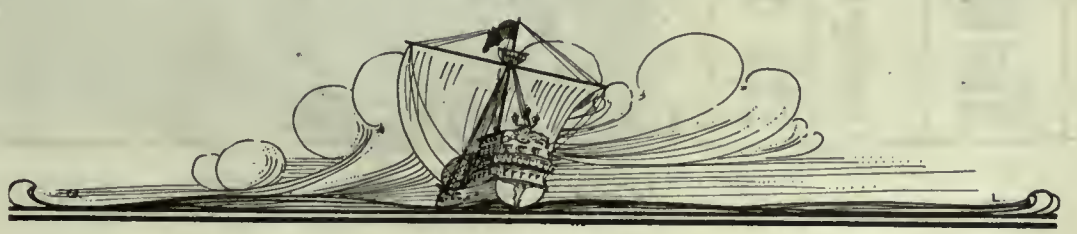
As for Grogan his story is different. He had luckily made the most of his time, and knew the requirements of the plant like a book. He not only held his position but made a wonderful success of it, saving the firm thousands of dollars through his insight and experience. A notice was posted on the bulletin board to the effect that Grogan was to be retained in his present capacity, and the reasons for his success were given. "Grogan has made good," read the notice, "because he has made the most of his time in the shop. He has saved the firm considerable money since his appointment. This he has done because he knows our requirements. For some time past we have heard rumors of unfair treatment to our employes. Any such employe who has a reasonable complaint can see the manager any evening at his home, and will be given a chance to prove himself. Above all the firm wish their men to be satisfied."

After the posting of this notice I waited breathlessly, yea, almost anxiously, for the result. Would a stream of dissatisfied workers call at my home, or would only a few take advantage of this opportunity to unload their troubles? I needed Good Judgment and Courage very much, but they both assured me the posting of the notice was a wise move.

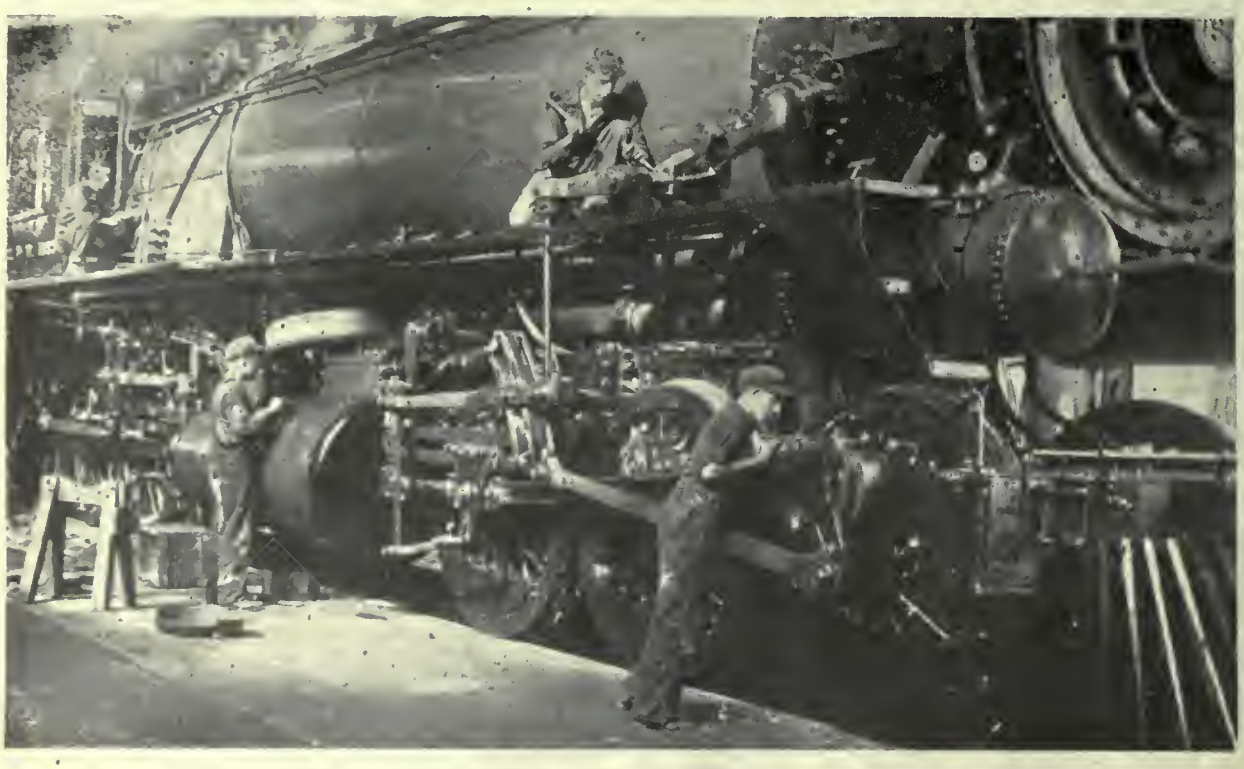
So far, no one has called. Evidently my workers are more satisfied than formerly. Six months have passed since the posting of the notice, and production has soared wonderfully in that time. The results coming from the automatic department are especially good. As I expected, Waeburn and Smith make a great combination, and what's more, they work together. I take no unfair advantage of any man in the plant. Every one who makes a suggestion is thanked for it, and if adopted is rewarded accordingly. Courage and Good Judgment still stick with me, in fact I told them the other night they must never leave me, and they laughingly told me, that depended entirely upon myself. A rather fine answer when you think it over.

* * *

Has the above story impressed you? True, it is imaginary, but after all what is labor unrest? Is it not also imaginary trouble. Men are always aiming at the position they think they would like, not to make better the job they have. Let us get more of the spirit to make good on the job we've got, and the higher position will come; when we ourselves are ready for it.



Systematic Control of Locomotive Repairs



THE FINISHING TOUCHES TO THE ENGINE, JUST PREVIOUS TO ITS LEAVING THE SHOP.

By J. H. Rodgers

THE wide and varied detail work that is required in the repairing of locomotives would seem to present, particularly to the layman, an engineering problem where considerable difficulty might be experienced in obtaining a satisfactory solution by adopting any systematic method of pre-arranged classification of repairs on each and every locomotive as it is taken into the shop.

Three score years and ten are set down as the allotted age of man, but his own weaknesses, and the uncertainties of life, provide many opportunities for relentless fate to place him under the care of a physician or in the hospital, for varied periods, to undergo light or heavy repair, or general rebuilding. Locomotives are not unlike human beings in this respect. The periodical "life" of a locomotive is estimated on a mileage basis, this depreciating as life is extended, and while many engines may, and frequently do, cover the scheduled distance before being shopped a great number must necessarily be taken out of service at irregular intervals and placed in the shops to undergo "hospital" treatment, in order to fit them for the service they are called upon to perform.

Engines may be taken off the road for one, or more, of a multitude of causes, and it is this varied combination of "infirmities" that has, until recently, made it so perplexing to draw up effective repair schedules. The principles of production control have been universally practised for many years by large manufacturing industries, but apart from localized effort in some particular department no general organized movement has been made by railway companies to prove its adaptability to general repair activities.

In the case of new equipment units, where the work, from the rail up, is that of straight manufacture, the problem

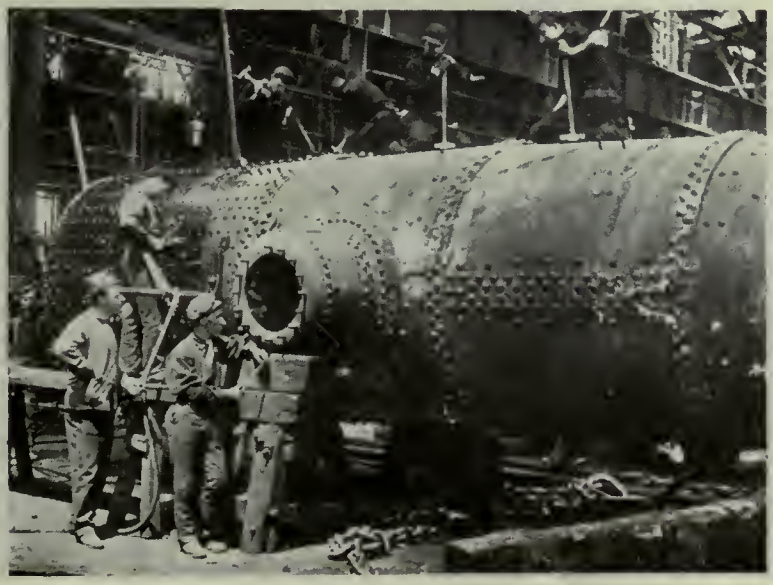
does not present any serious obstacles, but on repair work—and this constitutes the bulk of any railroad shop activity—the inauguration and subsequent successful operation of an efficient production control system, is, apparently, encompassed with such complicacy that considerable courage and executive ability are fundamentally essentiol, on the part of those in charge, before the work can be carried on with any degree of permanen success.

The Canadian Pacific Railway is probably the pioneer railroad company to recognize the economic possibilities from a well-organized production department, not alone in the construction of new locomotives, freight and passenger cars, but also in the general repair and maintenance of all motive power and rolling stock passing through the shop. When the system was initiated at Angus shops, nearly three years ago, it was not started on an experimental basis. The executive heads, believing that systematic methods from a production standpoint could be successfully applied to railroad repair work as well as other lines of industry, placed the control of the organization work in the hands of capable and experienced officials, to "establish the department on a firm foundation so that future building would improve, and not detract from, the strength of the structure.

The estimated repairs to any locomotive is based on the road report and the initial inspection made by the shops inspector and the general shop foreman. It might be stated that road requirements, to a large extent, determine the particular engines that are to be taken into the shops from time to time. Under normal conditions engines would take their turn on a mileage basis in being shopped, but urgent demands are often made for extra output of a certain class of passenger or freight engine which must be met irrespective of any regular order.



A VIEW SHOWING A PORTION OF A BOILER UNDERGOING REPAIRS.

After the preliminary examination the engine repairs are classified as 4A, 3B, 1C, etc. At Angus these classifications are indicated as follows: No. 1, new boiler; No. 2, new firebox; No. 3, any new firebox sheet; No. 4, all tubes; No. 5, 2-inch tubes; No. 6, specific repairs. With the exception of No. 6, all repairs include the replacement, or re-turning of the tyres, and general inspection and necessary repairing of all engine parts. Suffixes are used in conjunction with repair classification to indicate work not otherwise specified. These suffixes are: A, denotes wreck; B, denotes initial application of stoker; C, denotes initial application of superheater; D, denotes initial application of valve gear; E, denotes conversion from compound to simple, or vice versa.

For instance, if an engine, after preliminary inspection, is found to require a new set of tubes throughout, and to have a stoker applied, she will be classified as a No. 4B repair, and this symbol will be placed on all charts and correspondence in connection with the work on that particular engine; 2C would in-

FIG. 3—A SUMMARY FORM OF AN 18-DAY SCHEDULE.

dicate that repairs called for a new firebox and the initial application of a superheater.

The form shown in Fig. 1 is that for the repair engine output. This specifies

the gang and the foreman in whose charge the engine has been placed, and the date the engine is to be delivered. These forms are made out for a period of thirty-one days but are revised weekly to conform to changes necessary in the schedule. These alterations, when necessary, are made after the engine has been a couple of days in the shop. The reason for this is due to the fact that the preliminary inspection does not always disclose the exact nature of the total repairs required. This can only be determined after the hydrostatic test has been made, which is carried out after the motion work has been dismantled and the driving wheels and truck have been removed. This pressure test, together with a closer physical examination, either confirms the first inspection, or brings to light additional defects, the latter invariably being confined to boiler conditions.

In the preliminary inspection the engine may have been classed as a No. 4 repair, but when subjected to the cold water test, may develop further firebox or boiler trouble, calling for the renewal of a firebox or throat sheet, or perhaps an entire new firebox. Should such conditions arise, it becomes necessary to reclassify the engine as a No. 3 or No. 2 repair; in which case readjustment of schedule becomes imperative, so as to coordinate the work of the different departments to which the various parts of the engine have been distributed.

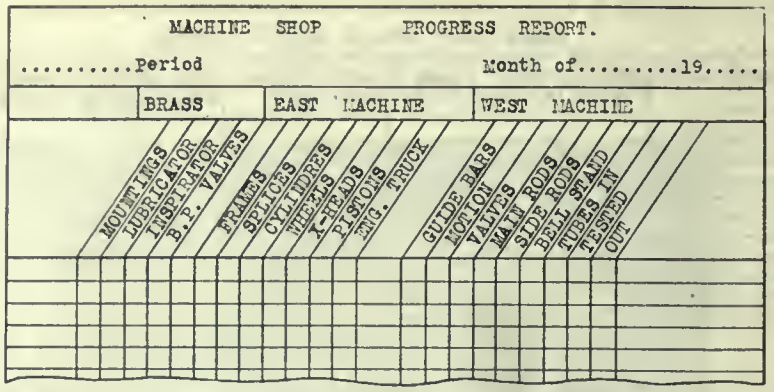

FIG. 5—THIS FORM SERVES AS A CHECK ON THE PROGRESS OF WORK PASSING THROUGH THE MACHINE SHOPS.

Under ordinary conditions locomotive repairs at Angus are based on an eighteen-day schedule. Cases are on record where engines have been overhauled and delivered in fourteen days, but the general time ranges from sixteen to thirty days, depending on the special work required. In every case, the first four days of dismantling and the last seven days of erection are practically identical on all engines, these periods having become fixed items in all repair schedules, The hydro-test on the boiler is the main factor in determining the "in-between-period," as all other repair requirements can usually be classified before the engine enters the shop.

However, once the patient is taken into the hospital and assigned a bed, the true nature of his illness and the character of the operation necessary can only be definitely decided after professional diagnosis and X-ray examination.

When changes are made in repair schedule, due to the developments of additional defects, it necessitates prompt action on the part of the schedule department in notifying all divisions of the shop that this particular engine has been "set back"; that is, her delivery date has been extended to conform to the new conditions. If this means that a delay of several days will be necessary, work on detail repairs on that engine must be suspended and the effort directed to work that is required. It is useless to provide clothes for a sick man until he is well enough to put them on. It might

TUNING UP THE LOCOMOTIVE BEFORE GOING ON A RUNNING TEST.

be said that it is good policy to have the garments ready. This would be true if it was not for the fact that another man was being kept in bed a day or two longer because his clothes were not at hand. Idle locomotives are items of expense on a railroad company's cost sheets. In order, therefore, to maintain the monthly output from the shop, it is necessary to so arrange the incoming engines that ample provision may be made for extended repairs to one previously taken in.

When an engine has been "set back" on schedule another one is advanced, and the different departments are advised as to the changes effected. The small form shown in Fig. 2 is used for this purpose.

On the ordinary repair, detail work on certain engines is carried on simultaneously in all departments during the period of dismantling and the erection date for each particular piece of equipment. A summary of an eighteen-day schedule is shown in Fig. 3, this representing a No. 4 repair. The first four days' work, which is the same for all engines, comprises: First day—taking the engine in the shop, hoisting the engine and removing the wheels; second day—cold water test and general stripping operations; third day—material and parts delivered to different departments and the headers taken out; fourth day—tubes taken out and cylinder and valve bushes inspected. For the next seven days repair work is proceeding in each and every department so that on the eleventh day—or in the case of more extensive repairs, on the seventh day prior to scheduled date of engine delivery—work is started on reassembly and erection, which on the form here shown is being performed on the dates included between the eleventh and the eighteenth day, the latter corresponding to the date on which the engine is again placed in commission.

FIG. 7—THIS FORM SHOWS DELIVERY DATES OF MATERIAL TO ERECTING SHOP.

In order that the entire program of repairs may proceed with uniform regularity and insure delivery to the erection shop on or before the date specified, progress sheets are kept constantly up to date, so that a glance at the day's report will show the actual conditions as they exist. If any particular department has "fallen down" on the schedule, the schedule man loses no time in making an investigation, with the result that the cause of the delay is located, reported, and recorded, and immediate steps taken to remedy the trouble. A portion of one of these progress sheets (for the week ending Dec. 4) is shown in Fig. 4. Every shop foreman, and every other department head, is given one of these sheets, so that he is constantly advised of changes in the schedule and the delivery date of each engine. This enables him to so regulate his work that his own shop schedule will not fall behind, unless it be for causes beyond his control; in which case the schedule man has knowledge of it before it is a day old, and every effort is made to adjust the irregularity. The responsibility of this adjustment is one of the routine features of the production department.

The form shown in Fig. 5 serves as a check on the progress of the work pass-

ing through the machine shops. Provision is made for thirty-two engines and check marks are made in the small squares when machine work on that specific part has been completed. These progress sheets are collected daily by the schedule man and the progress recorded on the reference charts kept in the office of the supervisor of production. A section of the form used for recording the date of delivery of finished material from the West machine shop to the erecting shop is shown in Fig. 6. The material list contains 38 separate items, these being component parts of the equipment shown in the third division of the machine shop progress report. In conjunction with the two last mentioned reports, loose-leaf, letter size, typewritten reports are compiled for the current week, showing the delivery dates to the erecting shop, of the various units for all engines on that week's schedule. Included in the report is the equipment still due and also what is required for the first two days of the following week; this latter serves as a guide when making up the report for the next period. Appended to this report is a list of the engines due to be completed that week. This form is shown in Fig. 7.

When new cylinders are required in the specified repairs to an engine, the production of these is so scheduled that they will be cast, machined, and delivered to the erecting shop at the proper time for reassembly. The charge hand has no personal worries as to where he will get the work, does not require to visit the machine shop to see if the cylinder is ready, nor has he to take the responsibility of getting the cylinder to the erecting shop after the work is done. Every detail, apart from the actual duties of the men, is taken care of by the production department.

The form used for grey iron foundry work on cylinders is shown in Fig. 8. This gives the requisition number, pattern number, engine or shop order number, and the various operations necessary in the making and cleaning of the casting. This schedule provides for delivery of the rough cylinder to the machine shop, eight working days after the order has been given to the foundry foreman. If it should so happen that the shaking out takes place on a Saturday, the cooling would take place over the week end, and in this way one full day would be saved

In every branch of repair work carried on at Angus, the object has been to so co-ordinate the tasks of the various departments that a spirit of harmony pervades the entire organization. As the inauguration of the present system proceeded it became more and more evident to all foremen and supervisors, that because certain of their duties (which might be classified as clerical duties) were transferred to the production department they suffered no loss of prestige or position, and the real effect was to enable the foremen to spend more time in their shops in supervising the men, getting out the required work and doing it right.

The production department acts in the capacity of a clearing house for shops' information on output, and it obviously follows that the routing of work and the tracing of material to the shops can be better done by specialists than by foremen whose time can be spent to better advantage in the shops.

A Score Board to *Prevent* Accidents

How the Dodge Mfg. Co. Have Secured the Co-operation of Their Men in an Effort to Keep Down the Number of Accidents —Falling Off in the Hours Lost Through Injuries to Workmen

By HARRY BOTSFORD, Dodge Mfg. Co.

IT has been eight years since the Dodge Manufacturing Company of Mishawaka, Indiana, first started its accident score board. During this period we have answered thousands of letters from firms all over the United States asking for methods of operation, explanations and comparisons. Believing that our method is unique, interesting and worth-while, we are glad to give other manufacturers our experience with our sign board.

In the first place when the sign board was erected and planned there was no thought of the pioneering work that the Dodge Manufacturing Company was doing in welfare work. Our sole idea was to develop some means of cutting down preventable accidents in every department in our plant. W. L. Chandler, our Supervisor of Insurance, decided the best plan to do this would probably be to make use of a competitive spirit in workmen and foremen. Today, after eight years of operation, the score board is as much a pride to the worker-personnel as is a record-breaking pulley or transmission equipment. One represents an achievement in human conservation and the other marks a mile stone in mechanical progress—both of which are vitally essential.

The size of the board as we erected it just inside the main gate of our No. 1 plant was 17 feet x 24 feet, which gave plenty of room for large lettering. The mechanism for scoring points is as simple and fair as possible. The starting point is 1000, both for year and for month; each division is penalized according to its accidents; each day's absence bears a percentage charge in proportion to the total number of "men-days" per month per division.

How Factory Is Divided

Our departments were divided into 26 divisions, according to the various degrees of natural hazard of variation in numbers of men employed. The degree of hazard is disregarded in our business which covers the same general subject throughout the plant; the differentiation being considered as equalized in the choice or selection of men with reference to their ability and fitness for their respective class of work.

As to the variation in the sizes and groups of workers, we set this by establishing a differential charge per man per day for time off—which is computed by reducing each

division to men-days for each month, and using a multiplier of 10 to raise the figures to a more workable and understandable basis.

This system of scoring was finally arrived at after considerable experimental work and the present system seems to be fair in every respect and we have had no occasion to change it during the past few years in spite of the fact that during this time almost every known condition has cropped up.

In the fourth column of this score board will be noticed the figures which represent deductions for absence in that division.

Perhaps we have been too tolerant of the minor accidents which do not necessarily entail the loss of an appreciable length of time, as we do not penalize for any loss of time on the day of the accident. It is possible, however, by this means to secure a prompt report of all accidents, however small, so that we may be sure of proper attendance, and avoid, as far as possible, such suffering as may be otherwise charged to secrecy on the part of either men or division superintendents.

The Reward Comes Each Year

At the end of each year the employees of the divisions scoring 1000 receive two days extra pay, or such part of that amount as their time and employment bears to a full year. If none score 1000, then the highest ranking division receive the two days pay. General foremen of any division under them earning these premiums also participate on the same basis, but may earn but one prize if other divisions under them make a perfect score.

Our original plan was to distribute $25 in cash each month to all foremen of divisions winning perfect scores, but due to the relative importance and the efforts of the foremen with a widely varying number of men to deal with, we were, in all fairness, obliged to change this arrangement so that one-half of each prize is paid on a flat basis and one-half distributed according to the number of men overseen; thus a foreman in charge of 50 men will get a proportionately larger premium than the one in charge of 10 men.

It will be noted that the cash prize is small, and to some it may be even considered as trivial, but it was our intention not to make the men strive only to secure the cash prize as much as to awaken in them a healthy competitive spirit. In this we have succeeded beyond our fondest hopes for the competition is keen and constant.

Every member of each division is keenly alive to the fact that responsibility for keeping his division with a perfect score rests squarely on him—consequently, he gauges his work and actions to conform with all the precepts of safety-first. This interest is stimulated and fostered by making up the yearly basis out of the monthly average. The great thought is then concentrated on the yearly contest, and the discouragement of any unfavorable monthly showing is avoided because any other division may have a penalty sufficient in some months throughout the year to equalize these unfavorable periodical conditions.

Competition Is Often Keen

So keen does the competition become that more than once considerable tact and diplomacy had to be used in some divisions where the carelessness of an individual caused a disabling accident.

As a means of preventing accidents the score board has rendered excellent service for us. It is no uncommon occurrence to have 10 divisions out of 26 showing perfect scores. Included in some of our perfect scores is our Steel Foundry where we make castings weighing as high as 50 tons. This work is usually classed as hazardous.

Some divisions have perfect scores year after year and there is hardly a single division that has not shown marked decrease in accidents during the past eight years.

In addition to the sign board we also maintain a safety first organization among our workers that deserves much credit for our extremely low accident experience in our many departments. We unquestionably recommend our plan to any manufacturer, and know any organization will find a similar plan to be well worth while.

Metal That Lubricates Itself

Now comes an inventor who says he has a metal which will run hot and which will not "seize" because he has found a way of combining graphite with it, so comments Popular Science Monthly. This is probably the first time that any one has succeeded in combining a non-metal with a metal. An alloy of aluminum and graphite is said to give better results than the usual phosphor-bronze-bearing alloy at the same speed and pressure.

Substitute for Copper

During the war Germany was hard pressed for copper electric conductors, and Von Bett, a physicist, suggested that sodium would be an acceptable substitute.

The conductivity of sodium is about equal to that of zinc and about one-third that of copper, but since the specific gravity of sodium is small, it is a better conductor, weight for weight, than any metal.

On the other hand, sodium has a very low melting point and cannot be drawn into wire. Moreover, it cannot be exposed to the air.

The experiment was made of filling thin-walled iron tubes, painted as a protection against rust, with fluid sodium, and it was successful.

Whether or not such conductors as these can be introduced commercially depends upon the possibility of drawing the tubes cheaply. Sodium is now made cheaply from common table salt by electrolysis.

The exportation of Portuguese salt before the war was chiefly to the Netherlands, France, Newfoundland, Norway, Sweden, and Ireland, says Engineer. After the war conditions changed; the Netherlands, Sweden, and Norway now buy mineral salt from Germany, and France makes its purchases from England. According to the American Consul-General at Lisbon, the annual production of salt in Portugal for export is 150,000 to 200,000 tons. The stocks of 1917 and 1918 are still unsold. In Norway the importation of salt will be eliminted soon, owing to the building of large electrical sea water evaporating plants for obtaining salt direct from the sea. The representatives of the Portuguese salt industry have called the attention of the Government to their difficulties.

In a paper recently read before the Institution of Automobile Engineers, Mr. B. H. Thomas gave some particulars concerning the repair of worn motor parts by means of electrically deposited iron. He stated that the bath that gave the most satisfactory results, was composed of 75 grammes of ferrous ammonium sulphate to 1 litre of water, with a current density of 1 amp. per 30 square centimetres. The work is suspended in the vat from a standard fixed to the bench and in order to ensure a uniform deposit the anode is moved about the work by means of a small motor. The best anode proved to be that made up of 16 S.W.G. Swedish iron wire wound into the form of a cylinder and thoroughly annealed. The temperature of the solution should be kept above 68 deg. Fah., and it is desirable to decant and settle it every three days or so to remove oxides of foreign matter, which cause roughness in the deposited metal

Looking Over the *Shipping* Situation

By T. H. FENNER, Editor Marine Engineering of Canada

LOOKING back over the past twelve months' activities in the maritime world they cannot be said to have been without interest, in fact in some ways they have been spectacular, but have gradually been slowing down as the year wore on, until now shipping has entered the doldrums. How long it will tack about there before catching the first whisper of the wind of prosperity, depends upon a number of factors, the chief and most uncertain one being the time when the world will settle down to work and produce.

The expected slump in freight rates has materialised, and as the writer has pointed out in previous articles, the more inexperienced among the operators of shipping have felt the pinch the most. At the same time, passenger rates have kept up their previous high level, and have in many cases advanced, and that they will keep this advance up, is most probable. The conditions governing in the freight world are altogether reversed in the case of the passenger vessels. In the shipbuilding trade, work is also falling off, after the gigantic efforts put forth by various nations during the past two years, and in many cases plants which cost millions to put down are practically abandoned, and of no use to anyone at the present time. In Canada, the year has been marked by the failure of some of the yards, and the prospects for the future are at the moment, none too bright. The position of shipping all over the world is that of passing through a period of depression, and its effect is shown in falling freights, cancellation of building contracts, and in the laying up of vessels to wait for better times. The passing of the legislation known as the Jones Act in the United States was attended with much excitement, but inasmuch as its provisions have not yet been put into force, and are probably destined to be shelved, matters are being left in status quo for the meantime. The United States Shipping Board has at the moment probably enough troubles on its hands to suit even its fire-eating chairman, Admiral Benson, who has been reappointed. France has found the possession of a Government owned fleet not an unmixed blessing and is considering ways and means of getting rid of it to private owners. The blighting hand of the Government is being gradually moved from British shipping, but the Ministry of Shipping still survives, much to the disgust of the shipowning fraternity, who are anxious to be unfettered in their efforts to rehabilitate themselves. If the events of the past twelve months have shown one thing more clearly than another, it is that a Government is incapable of carrying on a commercial adventure such as operating ships or railways. The good showing of the C.G.M.M. up to the present has been largely due to the fact that practical shipping men were appointed to the executive positions, and the Government left the management of the fleet in their hands. The management have shown their strong commonsense by linking up the C.G.M.M. with some of the strongest and most powerful lines in the old country, by which arrangement they are sure of the best facilities in the various ports abroad and in the U. K., and are also assured of valuable feeders for cargo at outside points where a new line would have great difficulty in getting a look in. Such is the general state of affairs at this time of writing, and it will be profitable and instructive to look a little more closely into details.

The World's Tonnage

We have heard a great deal of late about the tonnage of the world being greater than in the pre-war days of 1914. This is true, but it does not take into account the natural increase that would have taken place in normal times, nor the fact that a lot of tonnage is very old, and in some cases almost obsolete. There has been a very large amount of reconditioning carried out during the past year, many vessels which had no overhaul during the strenuous days of the war having been taken out of commission and re-fitted completely. Another feature is that for a long period following the armistice the efficiency of the shipping in use was very low.

This was due to congestion in the various world ports, necessitating long waits for unloading, and loading again. The congestion was caused in a great measure by restrictive methods pursued by labor, and by the natural difficulty in clearing warehouses and storage sheds from the accumulation of merchandise that had piled up during the period of Government control. The breakdown of land transportation during the same period contributed also to the general tie-up.

This condition is being cleared up now, but is still bad in spots. The result of all this was that many ships were actually in their loading and discharging ports for a greater period than they were actually on the voyage between ports. This meant that there were too few ships to carry on the business, and the costs being so high, freights went up by leaps and bounds to cover these extra costs.

Owing to poor fuel, and general rundownness, ships took longer to cover the same mileage than in normal times, and

all these factors contributed to make the efficiency of the merchant fleet very low. Another point is that a large percentage of the increase in the world's tonnage is represented by wooden vessels, which are mostly tied up at the present day, and represent a dead loss to their owners. The United States Shipping Board possesses about $200,000,000 worth of these vessels, which they can neither operate, sell, or even give away.

What the Figures Show

Comparing the figures for 1914 with those of the present day we see some points of interest. The totals are taken from Lloyd's Register of Shipping, which is the world authority on the matter. Vessels of less than 100 gross tons are not included, neither are warships. In 1914 the world possessed a total of 45,404,000 gross tons. The total in June, 1920, was 53,905,000, or a total increase of 8,501,000 tons. The relative position of the great shipowning nations has materially altered. For instance, in 1914 the United Kingdom had 18,892,000 tons, while the United States had only 4,287,000, including all her Great Lake craft. The percentage of the world's tonnage owned in the United Kingdom was 43.9, while that of the U. S. was 4.7. At the present day the percentage of the United Kingdom has decreased to 35.1, while the United States has increased to 24. The increase in the other countries has practically all taken place since the closing of the armistice, during which period the increase in the world's shipping has amounted to over 6,000,000 tons. By carefully estimating the net increase in the tonnage of the various nations, and eliminating all wooden and iron tonnage, the compilers of the Registry arrive at the conclusion that the world is still 3½ million tons to the bad as far as steel steamers are concerned. This effectually disposes of the claim that there is too much tonnage afloat.

Great Britain Still Building

The outstanding feature of the shipbuilding situation has been the increase in the number of vessels now under construction in the United Kingdom, and the decrease of those under construction in the United States. The building programme of the U.S. is now about finished. The same thing applies to the construction in Canada.

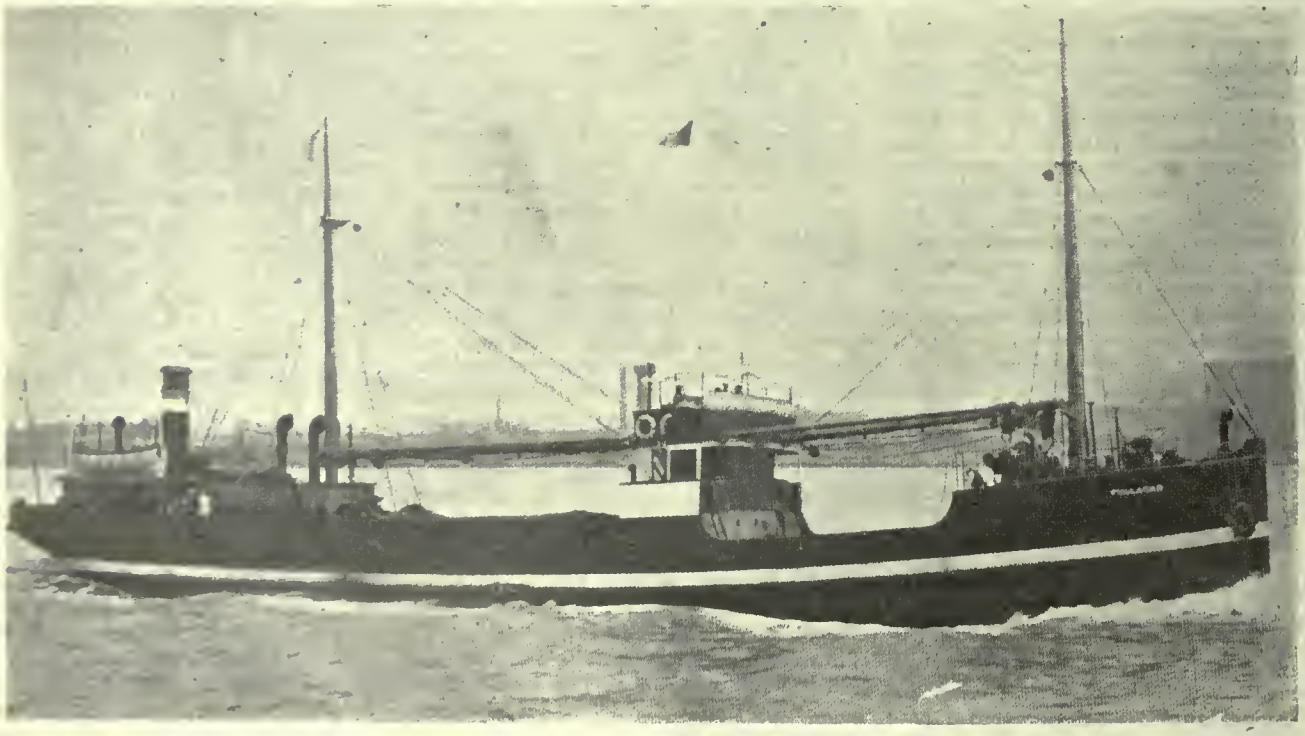
The following figures for the quarters ending March 31, June 30th and September 30th will give a good idea of the progress of events. There is no doubt that the immense amount of reconstruction work undertaken in the United Kingdom, as well as the dilatory attitude of labor, has kept production of new tonnage down, but even at that a very steady increase is noted.

In the quarter ending March 31st, the amount of new construction under weigh in the United Kingdom was 3,394,425 tons. This was made up as follows 814 steel steamers, 7 ferro-concrete, and 4 wood and composite steamers. There were also 35 steel sailing vessels, 4 ferro-concrete vessels and one wood and composite ship. In the United States at the same date there were 450 steel steamers, 29 wooden steamers, 10 steel sailing vessels, and 46 wooden sailing vessels, or a total of 535 vessels of all kinds, with a total tonnage of 2,573,298 tons. In Canada at the same date there were 50 steel steamers, or a total tonnage of 157,000 tons under construction.

Many Large Carriers Built

A notable feature of the steamers under construction in the United Kingdom was that there were 62 steamers of over 10,000 tons included. These were made up of 10 between 10,000 and 12,000 tons, 29 between 12,000 and 15,000 tons, 20 between 15,000 and 20,000 tons, and three between 20 and 25,000 tons. These vessels were mostly of the purely cargo, or the combined cargo and passenger type, very few companies building the purely passenger liner class of vessel.

In the following quarter, that ending June 30th, the figures altered to the advantage of the United Kingdom steel steamers were 888, ferro-concrete 3, and wood or composite 4. The sailing vessels were, steel 41, ferro-concrete 3, and wood or composite 2. The tonnage represented was 3,388,000. In the United States the steamers had fallen to 366 of steel, 18 of wood, while the sailing vessels were 15 steel and 16 wood. The total tonnage represented was 2,105,956. In Canada the tonnage under construction was 58 steel steamers, and 12 wooden steamers, and 14 wooden sailing ships. The total tonnage was just over 200,000. In Great Britain the steamers over 10,000 had gone up to 63, nine of them being between ten and twelve thousand, thirty-one between 12,000 and 15,000, the remainder being the same as in the previous quarter. The peak of Canadian building for the year had been reached in this quarter, as the next quarter shows a drop in the number and tonnage of the vessels on the stocks and being completed.



THIS VESSEL MARKED A GREAT DEVEVLOPMENT IN SHIPBUILDING. SHE IS ENTIRELY ELECTRIC WELDED AND FITTED WITH AN OPPOSED PISTON INTERNAL COMBUSTION ENGINE DESIGNED BY CAMMEL, LAIRD & CO.

The figures for the quarter ending December will of course show this still more, but they are not yet available.

What Other Periods Show

The quarter ending September 30th shows a still higher figure for Great Britain, and a further drop in the U.S. Thus the steel steamers in the United Kingdom numbered 912, ferro-concrete 5, and wood or composite 4. Their total tonnage was 3,720,000 while sailing vessel tonnage made another 11,000.

United States figures are 260 steel steamers, with a total tonnage of 1,734,000, wooden steamers being 12 of 18,000 tons and ten each of wooden and steel sailing vessels of 18,000 tons. There is thus a considerable decrease in the number and tonnage of all vessels building in the United States. In Canada the number of steel steamers had decreased to 46, with a tonnage of 158,000, three wooden steamers with a tonnage of only 1,057, and 15 wooden sailing vessels of a tonnage amounting to 11,000. Thus the figures show the gradual rise of British shipbuilding and the falling off of United States shipbuilding. The cause of the decrease, both in the U. S. and Canada is of course the completion of the Government building programmes. The United States now has a fleet of sea going merchant vessels operated partly by the Shipping Board and in part by private firms who have been allocated tonnage by the board. A large number of the vessels which were under private management have been handed back to the Shipping Board since the freight market fell in, and the Board has laid up a large number of their vessels which they have been unable to fix.

The United States Merchant Fleet

Probably the events of most interest in the year's operation of the now merchant marine in the United States, has been the passing of the Jones Act and the investigation of the Shipping Board. The Jones Act is the name given to the legislation introduced by Senator Jones, which had as its avowed object the bolstering up of the new merchant fleet against competition by the nations which were doing the most of the carrying trade. Chiefly, it was directed against Great Britain. The untoward events of the last five years having resulted in Great Britain losing a great portion of her shipping in the service, and for the benefit of the rest of the world, and the United States having become possessed, at enormous expense, of a more or less efficient fleet, it was felt by the Senator and those associated with him, that something had to be done to ensure its ability to live. Legislation passed in former years by Senator La Follette has resulted in making the ships of the U. S. the most expensive in the world to operate. This was on account of the extraordinary accommodation and living standard set for the U. S. seaman, and when this was coupled to the necessity of paying overtime for every little job that was done out of the regular routine, running ships at a profit even during the era of high freights was a problem.

It was not an uncommon thing for a Shipping Board vessel to arrive in a United States port with the bill for overtime to the crew totalling more than the actual wages, which themselves are very high.

Preference for U. S. Shipping

The method employed and backed by Admiral Benson, chairman of the Shipping Board, was to pass legislation by which all goods imported or exported to or from the U. S. in American ships should receive a preferential rate on the railroads, and also a preferential tariff. This meant that treaties in force with some twenty-nine other nations would have to be abrogated before this legislation could be put into operation. President Wilson, who even if he is an idealist, has a larger view than some of the U.S. senators, refused to give his assent to the bill, and it has hung fire ever since. It was not universally acclaimed even in the United States, the port of Seattle registering a very violent protest against its adoption. In reply to this Admiral Benson issued a statement that the protest was engineered by alien enemies of the United States, who wished harm to the new fleet, and threatened the port of Seattle with drastic punishment if their protests did not cease.

The claim of the Western seaport was that the bill, if put into effect, would ruin their trade. However, Admiral Benson has been made Chairman of the reconstituted Board, and with the coming into office of a new administration, pledged to further the interests of the U. S. mercantile marine against all comers, there will likely be some interesting developments in 1921. It is noteworthy that the British shipping press hail with satisfaction the reappointment of the bellicose Admiral, as if they feel that no worse harm could come to the Shipping Board fleet than having him in control.

What the Inquiries Showed

The investigation into the activities of the United States Shipping Board was undertaken by two former officers of the Board, and they have so far found that the Board committed everything but murder. Such things as incompetency, ignorance, graft, etc., are charged in connection with all its activities, and if half the charges are true, one can only sympathize with the great American nation. If half the blunders and mistakes that are charged could be committed by any body of presumably big business men in that land where efficiency is supposed to roost on the same perch as the eagle, how ever could any ordinary body of men be expected to succeed? The British press, which is naturally highly interested, is of the opinion that a lot of the charges are due to pre-election vigor. They take the view that when a totally inexperienced body like the U. S. Government take on a job like the building and operating of a huge merchant fleet, there were bound to be lots of mistakes, and the charges of graft they dismiss as due to the zeal of the investigators.

Competition Has Cut Rates

The vessels of the fleet have been put on various routes during the year, and have been in some cases responsible for the lowering of rates at a sudden clip. For instance, during the coal strike in England, when a new business in export coal sprang up suddenly from the Virginia ports, the board put such a number of ships on the trade that freight rates dropped rapidly. They also insisted on seeing the charter of any ships other than their own, American or foreign, so that they were in a position to know just what everybody else was doing, which of course gave them a considerable advantage. The deal by which Mr. Harriman has arranged a service between Hamburg and New York in connection with the old Hamburg-American line was consummated under the supervision of and with the consent of the Shipping Board. This gives the ships of the American corporation the advantages of Hamburg-American organization in Hamburg, but it also, in the opinion of a large number of people, gives the Hamburg-American line the entering wedge which they are looking for, in resuming active competition with the vessels of their erstwhile enemy. It is rather a peculiar thing that with the country still technically at war with the U. S., business arrangements can be made between German and American citizens, with the active help of a department of the American Government.

British Shipping

British shipping has been fighting its way back to its old time trades against a combination of handicaps which might well discourage any industry. The shipowners have been put to all kinds of inconvenience and expense by Government departments, notably the Ministry of Shipping, which having been created during the war, is doing its best to perpetuate a useless life. The Government has promised that its activities will shortly be discontinued, but it still drags on, and affords a proof if such were needed, of how hard it is to make men give up the easy hours and emoluments of a Government position, even when there is no possible excuse for their retaining them. The large liner companies have been reconditioning their ships, and getting them back on the routes, but it is notable that no companies are going in for the large fast passenger liner. Costs of building and operation have increased to such a point that the liner de luxe is a commercial impossibility.

Change in "Style" of Vessels

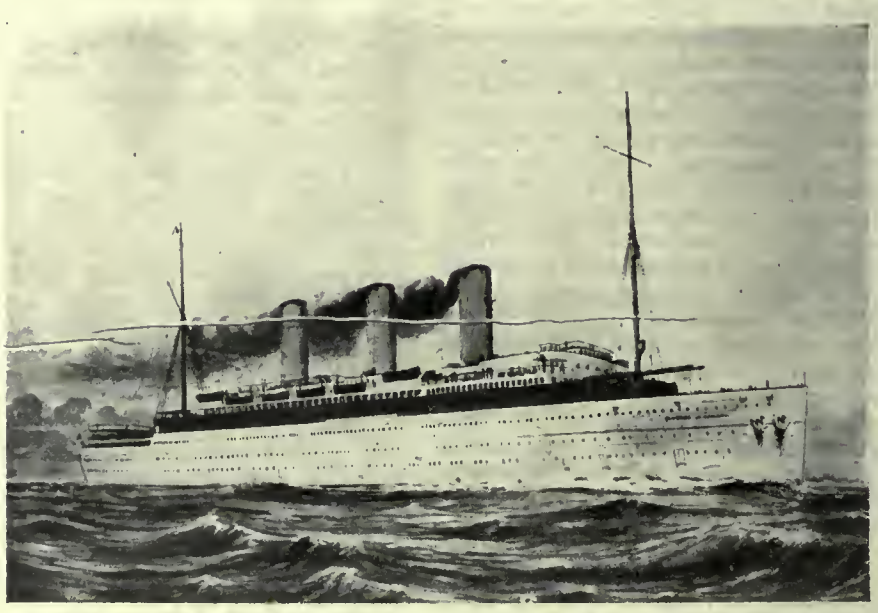
The type of vessel in favor now is the moderate size and moderate speed vessel that can give good accommodation to a fair number of passengers while carrying a large cargo. The shipowning business has been very badly hit by the low production of coal, and the embargoes placed on the export of coal to foreign countries, and the export of bunker coal. It is of course well known that the bulk of the steamers leaving England in the past have had cargoes of coal, which they took to all parts of the world, bringing back the produce of those countries. The coal formed outward freight and also created credits to pay for the goods brought back to the United Kingdom from other countries. The attitude of the coal miners in restraining production of coal, and the vexatious delays and restrictions placed on steamers by the Government department which has control of coal, has resulted in vessels having to leave England in ballast, to make long voyages in many cases, in order to get a return cargo. This resulted in high freight rates, which made the price of all goods brought back still dearer to the people in England.

During the coal strike, coal was actually imported to Britain, but worse still, the market in France and the Mediterreanen which had always been supplied by Britain was opened to her competitors.

Building Costs are Away Up

Costs of shipbuilding have gone to such a pitch that many firms have paid large sums to cancel the contracts for ships they had under construction, rather than continue with them and have to pay an exhorbitant price. With falling freights, it is impossible to run the ships at a profit when the capital cost is abnormally high. In this connection some very straight words have recently been delivered to the workmen in the British yards. They have been told plainly that they are hanging back and not delivering an hour's work for an hour's pay, and that if this continues they will soon be without a job of any kind. A very serious side of the high cost, and not only the high cost, but the altogether unnecessary length of time taken is that it has resulted in a large amount of repair work being sent to the Continent that should have been done in the United Kingdom. A number of contracts for ships received from Norwegian and other foreign shipowners have been cancelled, but this is probably not so much a matter of high costs, as the slump in freights, which make it appear a bad time to acquire new tonnage. At a recent launch of a Cunard steamer, the Chairman of the company said that the vessel was six months late in delivery, and had cost in excess of her estimated cost a matter of nearly $3,000,000. This sort of thing is naturally a big handicap. There is one thing that is to be said as far as the British shipowners are concerned, they have been through hard times before, and know just how to face them, and where to squeeze a living for a ship if it can be done.

If labor will assume anything like a reasonable attitude, especially the men actually sailing the ships, Great Britain will pull through the present depression in better shape than most of her competitors, and be on hand when the good period comes round again. There is no doubt that if the world in general were functioning properly, there would be ample work for all the ships at present afloat, and for a good many more. The elimination of a huge country like Russia from the trading field of the world has had a disastrous effect on many other countries, and the low rate of foreign exchange has also been a handicap on trading. British shipowners generally ask for nothing but a relief from the irritating restrictions of incompetent and stupid Government officials, and then they feel they can meet competition as they have hitherto done, and beat it.



ONE OF THE LATEST C.P.O.S. EMPRESSES—THE "EMPRESS OF CANADA."

Canada's Shipping and Ship-building

The past has been a busy year for Canada, both in her shipbuilding yards and on the high seas. Besides the ships that have been built for the Canadian Government Merchant Marine there have been a few built for export, and there is no doubt that there could be more export orders secured if there was any method of overcoming the exchange rate handicap. It has been rumored on several occasions that large orders have been secured for vessels for export, but these have not materialized. A suggestion was made during the year that the Government should finance the building of ships for foreign order, taking a mortgage on the vessel as security. This was finally agreed to by the Government, but up to the present no orders have materialized under this arrangement. Shipbuilders claim that the proportion of the cost of construction that would be advanced by the Government should be about 50% instead of the 25% they suggest. At the present time building is active at Halifax, Levis, Three Rivers, and Port Arthur and Collingwood. Some of the Pacific coast yards are also building vessels.

At to the outlook for the future we quote the opinion of one of the leading men in the industry, which should be of interest as coming from a practical shipbuilder, who knows whereof he speaks. The gentleman in question is Mr. C. M. Gillam, managing director of Canadian Vickers Ltd., who speaks as follows:

"During the past year the supply of materials, especially steel, was considerably handicapped by the labor troubles in the States in the railroad and mining industries, but this condition has much improved in the past few months. The tendency now as regards prices is downwards in practically all commodities. The supply of materials is distinctly good and promises to improve.

"There is an ample supply of labor and its efficiency has shown a steady improvement, although the wages which gradually increased during the past years to meet the increased cost of living, still remain at a high figure. In this connection it is confidently hoped that as the cost of living improves the saner elements in labor will be able to guide their less informed brothers, realizing that a reduction in labor costs is essential if business is to be obtained in competition with European countries.

"In the shipbuilding industry there is a serious falling off in the number of employes, due to lack of orders for 1921. The cause of this is the adverse exchange rate and the fact that the Canadian Government shipbuilding programme has come to an end. There is no market in the

United States for Canadian built ships due to the financial inducements offered by the United States Government to United States owners to build their vessels in the States. The consequence is that the only market for Canadian shipbuilding at present is Europe and, as stated above, the exchange rate is sufficiently high to prevent business.

"With reduction in prices of materials and increasing efficiency of labor, prices asked for in Canada for ships are steadily coming down, and it is confidently predicted that, with the further reduction, both in wages and materials, anticipated in the near future, such prices will be so reduced as to enable Canada, apart from the exchange question, to compete to advantage in the open markets of the world. This is the only feature which justifies the hope that, as exchange becomes normal, there will continue to be a limited shipbuilding industry in Canada which can operate on a commercially sound basis.

"It should be noted in this connection that the cost of construction of ships in Canada is not materially higher than the present cost in England when the exchange situation is left out of account, although it must not be forgotten that there will undoubtedly be a tendency towards cheaper production in England when labor conditions there become more settled, although there is no likelihood of wages in Great Britain ever being reduced to pre-war rates.

"It is worthy of note that, roughly speaking, 50% of the business of Canadian Vickers, Limited, in shipbuilding has been for export, and the performances of ships built by them for foreign countries has more than justified the confidence in the ability of Canadian workmen and Canadian shipbuilders to turn out ships in all respects equal to those of any other country.

"The outlook for 1921 is not bright at present, so far as shipbuilding is concerned, but the basic factors, namely—efficiency of labor, the drop in price of materials, and the recognition by labor of the economic situation and willingness on their part to co-operate to overcome the adverse features, are such that a pessimistic cessation of effort to overcome these difficulties and to tide over the dull period is not justified, but a more vigorous attempt is necessary on the part of the Government and employers towards finding means by which the industry may be kept alive until exchange becomes normal and the Canadian shipbuilding industry has a real chance to continue on its own merits.

"In conclusion, in our opinion the present situation of the shipbuilding industry is such that, provided the difficulty of exchange which, after all, is an abnormal one due to the war, can be overcome by means of assistance from the Government or otherwise, there is every reason to believe that shipbuilding in Canada can continue as a profitable commercial business."

The Canadian Government Fleet

Our Canadian Government fleet has extended its activities during the year until now it is on every route in the British empire. Vessels are sailing from Halifax and St. John, N.B., in the winter, and Montreal and Quebec in the summer to Newfoundland, Liverpool, European Continental ports, British West Indies, and South America, while they are sailing to the East Indies and China from both the East and West coasts. The vessels are a fine type of ship, well found, with good accommodation for officers and crew, and in the later ships extra accommodation has been provided for three or four passengers. On the ships in the Australian service refrigerating space will be provided, as well as the domestic refrigeration that is fitted in most of them. The writer, who spent a good many years at sea, has never seen ships with such comfortable crew accommodation as these Canadian vessels, and it is a credit to their designers. The fleet, as we have had occasion to mention on several occasions, is managed exactly in the manner of a privately owned line, and on that account has managed to show a very good profit so far. The action of the management in linking up their fleet with such firms as the Cunard Line, and Alfred Holt's, have shown a foresightedness and absence of the usual bureaucratic spirit associated with Government undertakings that gives the fleet a hope of success in the lean time to come. Canada has received a wonderful advertisement in all parts of the world through this excellent fleet, and it would have been well worth while from that viewpoint alone. Apart from this the fleet has opened up trade routes for Canada, and we believe has opened up the possibilities of export trade to many who had not previously given it a thought. The fleet is pretty nearly completely manned by Canadians, and is about as thoroughly Canadian an institution as can be found in the country.

The not inconsiderable lake and river traffic carried on by the Canadian Lake transportation companies has been bigger than ever this year, and it is pleasing to note that a purely lake steamer was launched for a Canadian company from the yard at Midland during the early part of December. This is a business which Canadian lake yards are as well able to handle as any others, and they should find much profitable work of this kind in the future. The repair business is well catered for in Canada, with dry docks at Sydney, Halifax, on the St. Lawrence, at Port Arthur, Collingwood and Midland on the Great Lakes, and in the near future on the Canadian Pacific coast.

Engineering Development

It is interesting to look over the development that has taken place during the year in the engine equipment of the new vessels built. While not wishing to take the attitude of "I told you so," it is pleasing to note that the prophecy we made as to the adoption of the oil engine is coming true. There is a gradually increasing number of shipowners adopting this type of motor, and it is not in small ships by any means that it is being adopted. It is pleasing to note in this connection that the large engineering firms in Great Britain are keeping well ahead in the internal combustion engine field, and have produced several interesting designs which have proved very successful. The companies which have adopted the internal combustion engine for their ships include such well-known names as Elder, Dempster & Co., T. & J. Brocklebank and the Glen Line of Glasgow. The number of vessels fitted with internal combustion engines now represents near 2% of the number in Lloyd's Register. Those burning oil fuel under boilers number 16.3%, while 76% use coal. The remainder are sailing vessels. There is little likelihood of the spread of the use of oil fuel to raise steam, as the price of oil is getting prohibitive for that purpose. It is not in the interests of conservation that oil should be largely used in this manner, as there is a large loss attending it. A good many vessels are fitted to burn either oil or coal under their boilers, and can change over from one to the other with little trouble, thus enabling them either to oil or coal their bunkers whichever is handiest, or cheapest.

The Geared Turbine in Favor

The geared turbine is also meeting with a large measure of favor, no less than 245 vessels of 1,286,046 tons being fitted with this class of machinery during the year. The reciprocating engine is still being put in a large number of ships, and there is no doubt that it will be in use for many years yet. Its record of reliability is something that will make many people cling to it till the newer forms have something of a record to show that can compare with the old three-legged job. The United States has experimented with ships fitted with the turbo-electric drive and have been sufficiently pleased with the results to decide on equipping a number of ships with this class of drive. It does not seem to have met with any favor in England or on the Continent. There seems to be a doubt if the extra weight and expense together with the complicated wiring, are justified in the ordinary cargo vessel.

There are, of course, certain advantages associated with the electric drive, notably in manoeuvring and in variable speeds, but for a cargo vessel these do not amount to much. The oil engine has developed to a point where it can be handled in manoeuvring as smartly as the triple expansion reciprocating, and nothing could be much handier than that. We do not anticipate the adoption of the electric drive in other countries than the United States.

There would seem to be little doubt but that shipping is in for a period of low

freights and hard times, and this will continue till the world settles down, if such a desirable consummation ever takes place. In circumstances like these, the only chance of survival is by practising the very bed rock of economy in the running of ships.

This means keeping personnel down to the minimum, quick turn round in every port, and the minimum of lost time for any cause. We believe the ship with oil engines will be far ahead of any of her rivals in this matter, but the number of them at present is so small that their effect on the general situation is small.

However they are increasing in a very steady manner, and in the next ten years it would not be a matter of surprise to see the major portion of the carrying fleet fitted in this manner. The next twelve months should bring some interesting developments in connection with the United States merchant fleet, which must be put on a commercial basis or go out of business. Just what method will be finally adopted to keep it afloat is hard to say, but we venture the opinion that enforcing the provisions of the Jones Act will do more harm to the new fleet than anything else that could be done.

The trouble is that the U. S. ship is costly to run, more so than any other nation ships, and there is no politician in the States with nerve enough to try and repeal the LaFollette Act. Even if there were, and he were successful, it is questionable if the ships could be manned with the special inducements removed. As it is, sailoring in United States ships is so desirable that numbers of men desert in U.S. ports from other country ships to get in on the good thing. There is no reason in the world why the United States should not have a merchant fleet, if sufficient people are interested in it, but to try and create a merchant fleet by eliminating the ships of all other nations from their ports, is to say the least a mistaken idea. The practice of withdrawing tonnage for a time, and then throwing it on the market in an effort to wipe out competition has also resulted in wiping out American companies which was not quite within the intention of the gentlemen who were doing the manipulating.

France has been handicapped in her shipping activities to a great extent by the coal strike in England. A large number of the French vessels were of the small collier type, expressly for carrying coal from South Wales to French ports. Naturally they have not been able to do much in this line. The large French transatlantic line is well under way again, after the cessation of the war. Italy has added considerably to her fleet, and has resumed all the services which she used to carry on. The Italians are experienced shipowners, and were possessed of some fine vessels before the war, and were among the heavy sufferers by the war. Japan has considerably increased her tonnage, but things are not too rosy in shipping circles in Nippon just now. Germany and Austria are of course still out of the reckoning as far as merchant shipping is concerned, although the arrangement made with the company of which Mr. Harriman is in control, points to the fact that the Hamburg-American line is not going to frozen out if they can help it.

This is not a time for prophesying, but more for hoping, and the hope is that the turmoil in Russia and other European countries will subside ere long and active trading commence between the various parts of the world. Only in that way will there be cargoes for the ships of all nations, work for the people of all nations, and an equitable exchange rate which will once more put commodities in the reach of people of moderate means. In short, a return to the normal is what we hope, but with a higher standard of living than obtained before the war. This is quite within reach, once the peoples of the different countries settle down to working instead of fighting. Let it be soon.

LAUNCHING A CANADIAN GOVERNMENT STEAMER AT COLLINGWOOD—THE "CANADIAN ROVER."

REDUCING CORROSION

According to D. M. Buck, metallurgical engineer for the American Sheet & Tin Plate Co., Pittsburgh, there is an overwhelming mass of evidence to prove that by allowing with normal open-hearth or Bessemer steel a small copper content—0.15 to 0.25 per cent.—the corrosion produced by air and moisture is greatly reduced. The melting point of copper is about 700 deg. Fah. lower than the average tapping temperature, it diffuses readily, and once diffused does not segregate.

The manufacture of copper steel has heretofore been largely confined to sheet metal, and the product has been greatly improved. A conservative estimate indicates that the life of sheet metal is at least doubled by this treatment, and in speaking of this subject he advocated the use of copper in all iron and steel products called upon to resist the attack of air and moisture.

It was stated at a symposium on refractories for electric furnaces held by the Electric Furnace Association, of Columbus, U. S. A., that refining furnaces, handling metal and corrosive slag at temperatures limited only by the melting point of the furnace itself, have about reached the limit of their possible development. It would appear that a new, cheap, dependable refractory with a melting point higher than 1750 deg. Cent. is now required, a substance which is highly resistant to sudden temperature variation so as to permit intermittent operation, which has been calcined at electric furnace temperature, and which, therefore, possesses reasonable constancy of volume. It must resist the scour of slag—or if a roof brick, must withstand the action of fume, hot gases, and splatters of liquid. It must be a poor conductor of electricity, or leakage of current may be serious. Finally, it must have sufficient strength at high temperatures to meet the requirements for the arches and side walls of the furnace.

A proposal is being considered, says the Engineer, to preserve the French supply of gun-cotton and nitrocellulose explosives — about 90,000 tons — by placing it in tanks at the bottom of a lake in the Pyrenees. Stored away at a safe and constant temperature, it is believed that the material would neither deteriorate nor decompose.

WELDING AND CUTTING

The Welding of Locomotive Fire Boxes

Welding Door and Flue Sheets, Patches on Firebox Sheets, Patches on Mudring, Door Collars, Knuckle Cracks, Building Up Worn Edges of Fire Box.

IN December 16th issue of Canadian Machinery we commenced this article by telling how full welded fireboxes, semi-welded fireboxes, and full welded, half side sheets were prepared and completed. In this the concluding portion of the article, we will touch on the subjects mentioned in the heading.

Welding Full-Welded Door and Flue Sheets

The method to be followed in preparing to weld door and flue sheets is similar to that described for full-welded fireboxes, as shown in Fig. 25. In the full-welding of door and flue sheets, however, the work is done on the inside at all the joints except the one with the crown sheet. That part of the welding is to be done on the water side, unless the radial staybolts are in the door sheet, when the welding must be completed from the inside.

First fit and bolt the door or flue sheet to the mudring. Next bevel both edges of the vertical joints on the inside, leaving a 3-16 in. opening at the bottom of the vee, see Fig. 26. Now bevel the joint with the crown sheet on the outside. The door and flue sheets should be flanged, as shown in Figs. 27, 28 and 29.

Tack weld the joint for an inch at R1, Fig. 25. Then drop down about 10 inches and weld from R2 up to R1, from R3 to R2, so continuing to R5 and welding last at A on the mudring.

Assuming that the radial staybolts are not in the door sheet, both the door sheet and the flue sheet should be welded on the water side to the crown sheet, starting at c, about 10 inches from R1, Fig. 25, and welding back to R1, from d to c, e to d, on over to L1 and then welding on the inside of the firebox from L2 up to L1, thus welding along until the sheet is finally completed at B on the mudring.

Welding Patches on Firebox Sheets

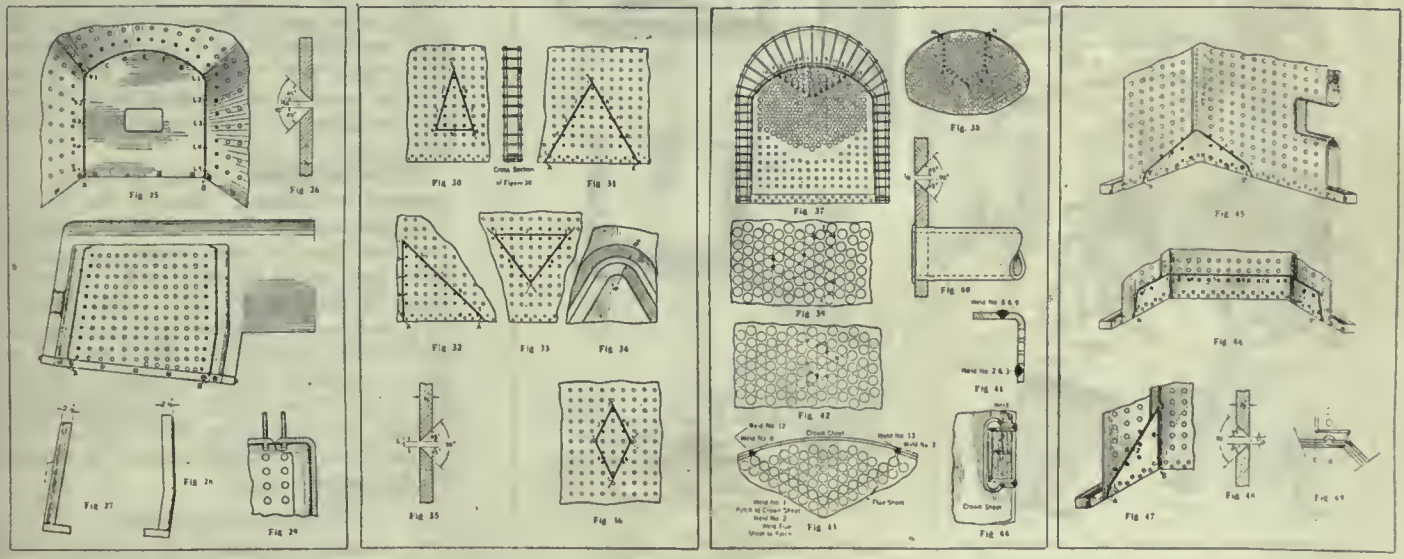
Patches for Firebox Sheets should be triangular in shape whenever possible, the reason being that the sides of the triangular patch do not run parallel with the rows of holes, and weaken the joint, as would a rectangular patch.

To weld the patch shown at Fig. 30, proceed as follows: Bevel the edges, then tack weld at 1. Then, beginning about 10 inches from 1 at 2, weld up to 1, from 3 to 2, and from 4 to 3. Let the joint become cold. Then weld from 5 to 4, and 6 to 5.

Preheat as shown at xxx1, to allow for expansion. Weld from 8 to 1, 7 to 8, and 6 to 7, and complete the job by preheating at xxx6.

To weld the patches shown at Figures 31 and 32, first bolt the plate to the mudring. After bevelling the edges, tack weld at 1. Then weld from 2 to 1, 3 to 2 on down to the mudring at 5. A, should be done last. When the weld is cold, preheat at xxx1, and weld from 6 to 1, 7 to 6 on down to the mudring at A.

In welding the patch shown at Fig. 33, proceed as follows: Preheat along xxx1. Then tack at 1 and weld over about 10 inches from 2 to 1 and 3 to 2. Let the plate get cold. Preheat again at xxx1 and weld from 4 to 1. Then preheat at xxx5 and weld from 5 to 4. Let the



THIS VIEW TAKES IN FIGS. 25 TO FIG. 49.

sheet get cold. Preheat at xxx3 and weld from 6 to 3. Again preheat at xxx5 and weld from 5 to 6.

Figure 34 shows the proper way to round the corners of the patches, using a radius of about ¾ in. In preparing all of the joints, use a bevel of about 45° and leave the vee open about 3-16 in. at the bottom, as shown in Figure 35. In using the diamond patch at Figure 36, the welding should be done in the same way as that described for the triangular patches. Expansion must be provided for by the proper preheating and reheating at the ends of the line of weld.

Welding Patches on Flue Sheets

The triangular shaped patch should be used for flue sheets wherever practicable. The method of applying the patches may be described as follows, the welding being done on the water side of the firebox:

Welding on Patch of Figure 37

First cut the flue sheet as shown in the drawing. Next weld the bridges at 1, Figure 37. Then weld from 2 back to 1 and from 3 to 1.

Weld the knuckle at 6 and then from 10 to 6. Then weld the knuckle at 7 and from 11 to 7. Complete the job by welding to the flange at 12 and 13.

The next patch, Figure 38, is for a deep job and requires less welding to the flange. In this case prepare the sheet as described for Figure 37. Weld the bridges at 1 and from 2 to 1. Then weld from 3 to 1, 4 to 2, 5 to 3 and so on until knuckles are welded at 8 and 9. Next weld the patch to the flange at 10 and 11.

To weld patch Figure 39, proceed as follows: Weld successively bridges 1, 2, 3, 4, 5, and 6. Preheat at ends of rows, and weld bridges 7, 8, 9 and so on until all are welded. All welds should be butt-jointed as shown in Figure 40.

To weld cracked bridges such as shown at Figure 42, first preheat bridges marked x at 1 and 2, then weld at these points, and reheat at x.

Welding Patches of Figures 43 and 44

First weld patch to crown sheet. Then weld flue sheet to patch as shown at 2 and 3 of Figure 41. Next weld flue sheet to crown sheet at 6 and 7 (see Fig. 43), using butt joint 8 and 9, Figure 41. Now weld to the flange at 12 and 13. A patch may now be welded to the crown sheet as shown in Figure 44.

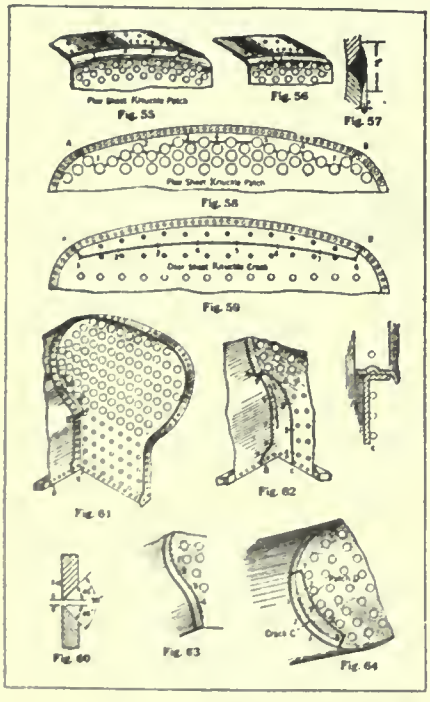
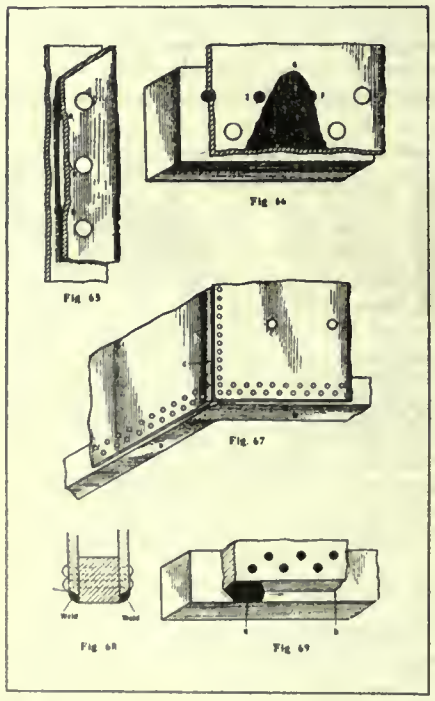
Fig. 52

FIGS. 50 TO 54 INCLUSIVE.





FIGS. 55 TO 69—SEE TEXT FOR DESCRIPTION

Welding Patches on Mudring

The following three methods of patching mudrings have proved to be most serviceable. Make sure that all rivets are left out adjacent to the weld. To weld the patch at Figure 45, proceed as follows: Weld from A to 1. Then weld from 2 to 1, and from 3 to 2. Next weld patch to flange at 3, Figure 45, as shown in detail at c and d, Figure 49. Then weld from 4 to 3 and on to B.

To weld patch shown at Figure 46, first weld from A to 1 on the mudring. Then back weld from 2 to 1, and allow weld to cool before welding from 3 to 2 and so along to 10. Complete the weld at B.

To weld on patch shown at Figure 47, proceed as follows: Remove the rivets adjacent to the weld on the mudring and side sheets, also remove the staybolts that would be affected by the heat. Start to weld at A. Then weld from 2 to 1, a distance of about 10 inches apart, and let the metal cool. Weld from 3 to 2, also welding to flange near 3. Then from 4 to 3 and B last. All weld joints should be beveled at 45 degrees and opened 3-16 in. at the bottom, as shown in Figure 48.

Welding Door Collars

In welding locomotive door collars the door sheet should be made large enough

to include a row of staybolts within its area, as shown in Figure 50. First bolt the patch in place by screwing in some of the staybolts, then bevel the edges of the weld joint at 45 degrees on the inside of the firebox.

Next tack weld for about an inch at 1 and 5, Figure 50. Now advance about 10 inches to 2 and back weld to 1. Weld from 3 to 2, 4 to 3 and 5 to 4. Next weld from 8 to 1, 7 to 8, 6 to 7 and 5 to 6. Figure 51 gives an end sectional view of the welded joint of a door collar.

Welding Door Holes

In welding door holes for locomotive fireboxes the butt weld of Figure 52 should be used. The work should be done as follows: Bevel the edges to 45 degrees and leave bottom of weld open about 3-16 inch. Next tack at 1, Figure 53; weld from 2 to 1, 3 to 2 and so on to 5. Then weld from 8 to 1, 7 to 8, 6 to 7 and 5 to 6. A lap weld like that of Figure 54 is sometimes used for welding door holes, but it should not be resorted to if the butt weld of Figure 52 can be made.

Welding of Knuckle Cracks and Patches in Door and Flue Sheets

In the following work the welding should be done on the water side of the firebox wherever possible. To weld the flue sheet knuckle crack of Figure 55, proceed as follows:

Preheat at xxx1, and tack weld at 1. Then start at 2 and back weld to 1, from 3 to 2, and 4 to 3. Reheat at xxx4.

In welding the flue sheet knuckle crack of Figure 56, first weld from flue sheet over knuckle to crown sheet on the water side of the firebox, and complete weld from the inside. This weld should be reinforced about 1-8 in. and widened to about 2 inches at the top of the vee, as shown in Figure 57.

To weld the flue sheet knuckle crack of Figure 58, first start to weld the flange at A, Figure 58, working on the inside of the firebox. Then weld on the water side from 1 to A, back weld from 2 to 1, 3 to 2 and so on to the flange at B.

In welding the door sheet knuckle crack of Figure 59, commence working from inside of firebox, and weld from 1 to A, back weld from 2 to 1, 3 to 2 and on across to 8 and B. The distance between tack points of weld should be about 10 inches. Figure 60 gives the form of vee for the butt weld. In welding the flue sheet patch of Figure 61, first weld the flange at A. Then back weld from 2 to 1, and on to B.

When welding a flue and side sheet patch such as shown at Figure 62, first cut the side sheet to outside of the rivet holes, as shown in drawing c. Weld the flange at A, and then back weld down to the flange at C. Now weld from 6 to 5, 7 to 6 and so on to B.

The flue sheet weld of Figure 63 should be performed as described for Figure 55, and the crack C of Figure 64 should be welded the same as that of Figure 55, while patch D may be welded in place by the method shown in Figure 61.

Building-up Worn Edges of Firebox

The edges of fireboxes become worn, and cause leaky joints, from excessive caulking, erosion from escaping steam and corrosion. The restoration of these edges by building-up may be accomplished as follows:

First refer to Figure 65. Brush the rust off the edge and build up from 1 to 2. Light hammering of the weld while red hot will improve the joint. At Figure 66, a piece rusted out as shown in this figure may be built up by first removing the rivets 1, 2 and 3, and then adding metal from A down to the bottom of the sheet to the mudring. The last example, Figure 67, is somewhat different. In welding sheets to a mudring build up the joint of the two sheets for about 5 inches above the bottom. Bevel the bottom of the sheets as shown in figures 68 and 69.

Welding Full-Welded Half Door Sheets

There are two methods used to weld in half door sheets of fireboxes. That shown in Figure 70 is sometimes resorted to to save time. It is not the best way to do the work, however. This method leaves the old riveted flange on the side sheets. The welding is done by starting at 1, back welding from 2 up to 1, and so on around, ending at B on the mudring. The most serviceable way to do the work is as shown in Figure 71.

The side sheet should be cut to the inner edge of the rivet holes, fitting the door sheet to the edge of the side sheet, and bevel the joints as shown in sketch at left of Figure 70.

Screw in the second row of staybolt holes, and bolt the door sheet to the mudring. Using a suitable tip and welding blowpipe with correct welding rod, start to weld at 1, Figure 71. Then weld the door sheet to the side sheet by welding from a point about 10 inches down at 2 up to 1, and from 3 to 2 and ending at A on the mudring. Back weld 10 inches from 6 to 1, from 7 to 6 and on around to B at the mudring. The sketch at the left of Figure 71 shows the style of joint between the door sheet and the side sheet.

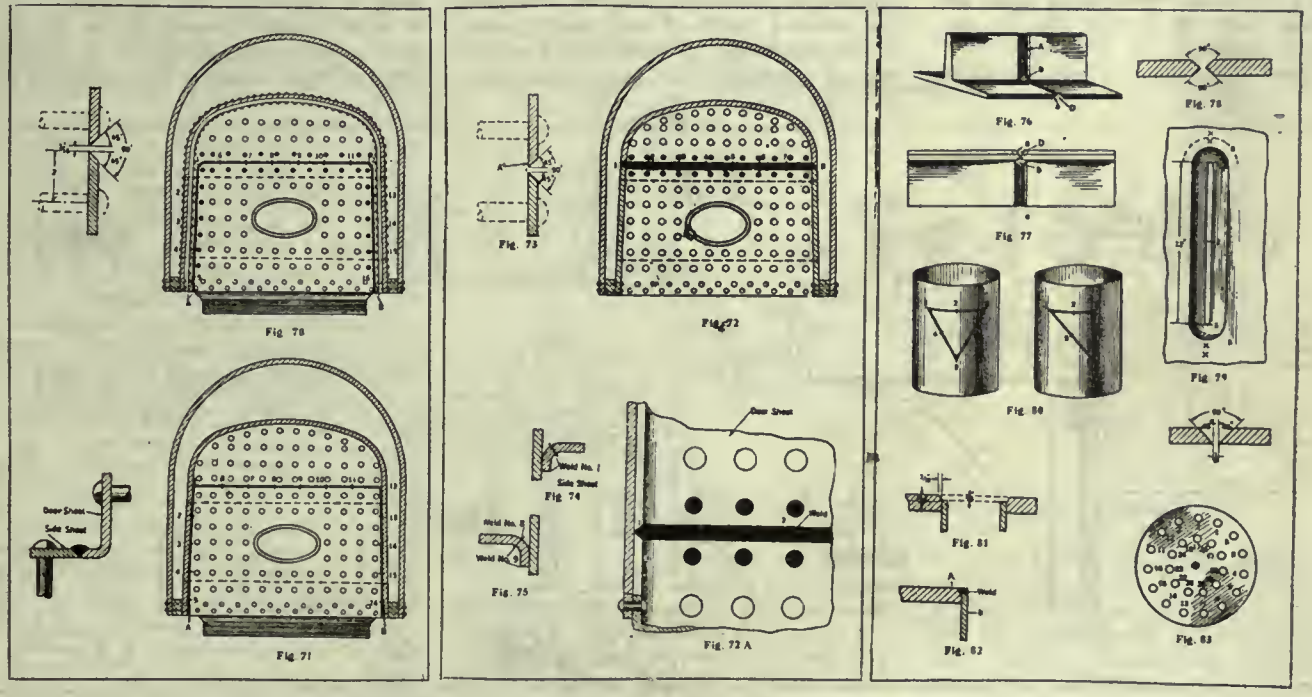


FIGS. 70 TO 83.—THIS CONCLUDES THE SKETCHES.

WHAT OUR READERS THINK AND DO

REDESIGNING SINGLE PURPOSE MACHINES

By G. Barrett

During the past two years we have heard a lot of talk regarding increased production, but are manufacturers taking the same interest in the development of jigs and fixtures that they did during the war period? There are a lot of old machines around the country at the present time that could be redesigned or modified for useful work. The accompanying sketch shows a special grinder constructed from an old single purpose shell machine. The headstock of this machine was removed and a knee bracket A bolted to the bed with the headstock on top. The vertical face of the knee bracket is provided with a dovetail slide to carry the movable table B, which carries the compound rest C and D, the latter being operated by means of a rack and pinion. Fixtures of different design may be used for a variety of work.

The sketch shows the machine adopted for the grinding of pulleys. The jig consists of a cast iron block E, shaped at an angle of 2 degrees, with a stud set in at right angles to the inclined face. The stud F is fitted with ball bearings to facilitate revolving when grinding. A cup wheel G is used and numerous sizes of pulleys can be economically produced in this way.

In some instances it might be advisable to finish turn after grinding. This could be accomplished by form turning, as shown in Fig. 2, where two or more pulleys are located on the one arbor and turned at the same time.

Sketch Fig. 3 shows a speed cone bracket used on a drill press. These brackets were originally planed, which proved both long and expensive. The fixture for holding these brackets while grinding is shown in Fig. 3, and is simple and costs little to make when compared to the production of brackets, which is about six per hour. A similar fixture is used for grinding the base of the pump bearing shown in Fig. 4. The piece is held to the locating pin, insuring the base being square with the bearing. Fig. 5 shows a fixture for the grinding of the yokes for clutches. This is made of cast iron with a V-block to support the lug on the yoke. Two small pins are provided to keep the face of the yoke in alignment with the wheel. These are only a few of many jobs that could be economically performed on a machine of this description, and it would be well for many firms to give a little attention to machines that have probably been relegated to the scrap heap, the remodeling of which would undoubtedly prove a profitable undertaking.

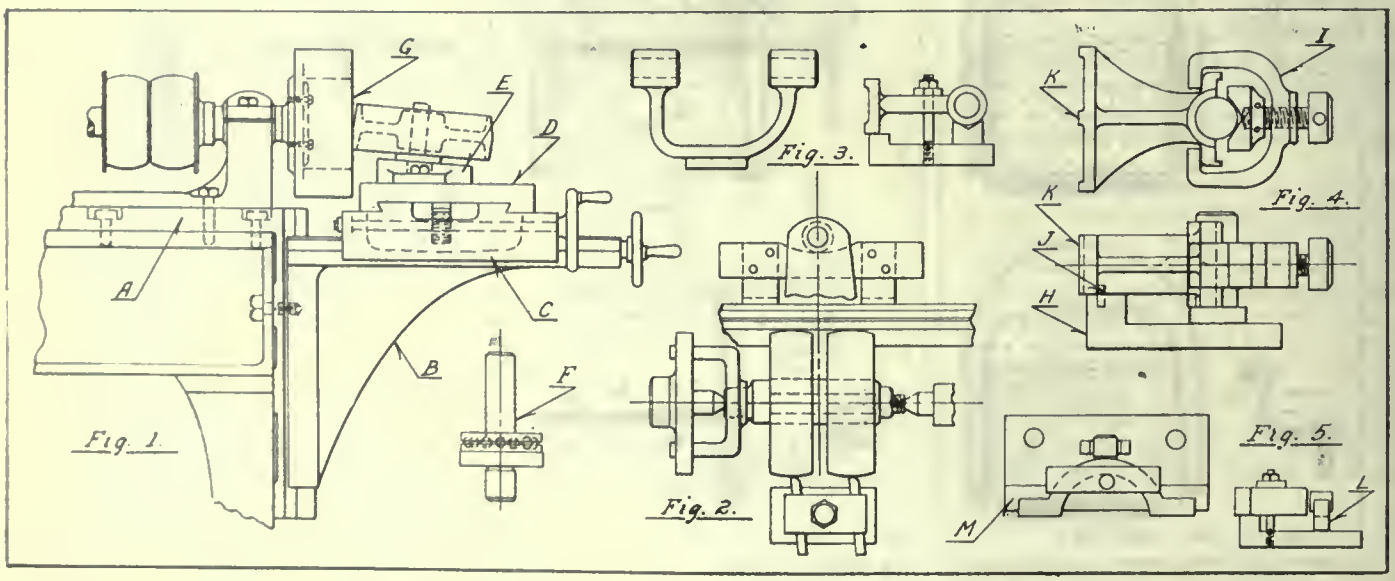
Editor's Note.—We believe this article raises a point of real merit, namely the possibility of modifying war time special machinery for peace time products. No doubt many readers have seen various installations of such nature, and we would welcome sketches and descriptions of the same.

STEEL CUTTING EDGES

By W. S. Standiford

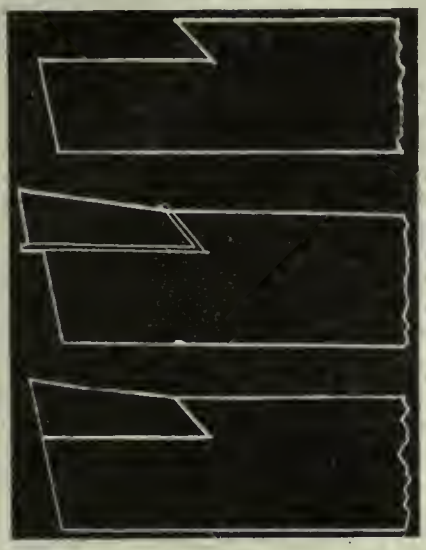
Probably one of the most useful and money saving metals that the machinery manufacturer reecives the greatest benefits from is high-speed steel. By having the tools for production work made out of this material a greater output has been secured at a lower cost per piece, in spite of the fact that this grade of steel is a very high priced one. The fine qualities of high speed steel are getting to be more generally known among the rank and file of business men, and in the last few years its price has risen to such an extent that it has become a matter of great importance to make a pound of steel produce as many tools as possible.

To use a solid tool made of high priced steel is very expensive, and in cases of this kind great satisfaction can be obtained by having a blacksmith forge a shank of ordinary machine steel, and weld or braze a small piece of the high speed metal on top of the shank to be used as a cutting tip. The great drawback to either welding or brazing work of this character, exists in the fact that it is a very difficult matter to secure a perfect union between the relatively soft



FIGS. 1 TO 5. SHOWING DETAILS OF THE SPECIAL GRINDER.

machine steel shank and piece of the high-speed metal so that it will withstand the heaviest roughing cuts that the machinery will allow. This is a necessity, as the greatest speed in doing work is obtained by cutting the roughing time down to its lowest possible limits; the production costs also being reduced by



HOW THE CUTTING EDGE IS PREPARED.

this method. By following the method outlined below, it will be found feasible to make a perfect union between the soft steel shank and the hard steel cutting tip that will give good satisfaction to the user of tool.

First forge the shank to its proper size and shape, and cut a slot in its top as shown in Fig. 1 of sufficient size as will allow of the insertion of a small piece of the extra hard metal to occupy this space, having the piece project out about 3-16 inch from the front and also 1-16 inch out from the sides of shank in order to allow for grinding after it is finished. It is also a good plan when making the shank to taper both front and sides at their bottoms. This facilitates quick grinding of the tool after hardening as a much smaller amount of metal has to be removed. The back end of both slot in shank and tool tip should be tapered to match. This makes it have a close contact when brazed and helps to keep the piece in position when a heavy strain is put on the front of the tool during the roughing cuts. Next cut a small piece of sheet copper about 1-32 inch thick to a slightly greater width and length than the bottom of slot that is shown in Fig. 1 and bend one end to fit the angle closely at the back of bar.

Brighten both the slot in tool shank and also copper strip with emery cloth or paper and treat the tip that is to be inserted the same way. Then coat both copper strip and the slot in machine steel bar with borax. Place tip over the copper piece and tie it tightly with wire so as to hold it in place during the heating operation. Fig. 2 depicts the tip placed over the sheet copper strip, no binding wires being shown in the picture. The tool is now put into a heating furnace and heated to the proper temperature recommended by the makers of the steel. When this is effected, remove tool and with quick blows of a hammer used on front of tip, drive the beveled part of tip into its seat, then quickly strike the high-speed steel piece a couple of moderately heavy blows. This distributes the melted copper and borax uniformly over the joint and at the same time causes the two metals to unite. Quickly plunge tool into the quenching bath and keep it moving until it is cold. Grind it to shape and it is ready for use in the lathe or planer. The combination of a machine steel shank with a piece of extra high grade and priced steel, produces a cheap, but efficient tool that will give good service if the brazing has been very carefully done. It is possible by this method to successfully unite various brands of high speed steels to machine steel shanks, although the writer has not tried whether "stellite" (which is said to contain no steel whatever) could be welded or brazed to shanks of a cheaper metal.

A NEAT REPAIR

By Tyke

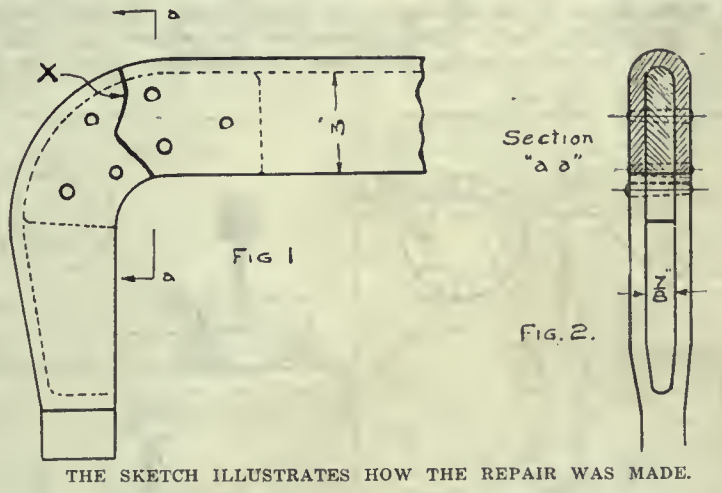
Some time ago the frame of a heavy duty power hack saw was broken at point "X" Fig. 1, due to an accidental obstruction of the stroke. The frame was of cast iron, and inverted U section. Due to this peculiar section and the small dimension between the inside of the U, it is doubtful if a really good welding job could have been made. In any case, it was decided to make a purely mechanical repair and the interesting part is that neither bolts nor rivets were used.

A forging of the proper shape and thickness was quickly made and simply ground on the high spots so that it could be tapped lightly into place, though no pretence at fitting was made. When the two pieces of the frame butted closely together, the frame and forging were clamped and drilled, then reamed for No. 8 taper pins which are approximately 1-2-in. diameter.

It will be noticed that these pins were not driven in from the same side, but were alternated, see Fig. 2. Furthermore, the holes were slightly eased in order to give the pins proper key draft and ensure proportional stresses on the pins. This precaution proved to be a wise one, as the draft not only ensured the broken ends of the frame butting properly, but increased the holding properties of the pins themselves.

After the pins were driven home, babbit metal was run into the frame about the forged piece in order to fill up any spaces that might exist due to any inequality of forging or casting. When cool, the pins were again lightly tapped to make sure they were tight and the frame assembled.

After many months' night and day work, the frame was carefully examined and the break was hardly perceptible and certainly no more so than the day it was repaired.



THE SKETCH ILLUSTRATES HOW THE REPAIR WAS MADE.

TRANSFERRING HOLES

By Harry Moore

Transferring of holes in various classes of work is of such common occurrence in the life of the average mechanic that a brief description of several well tried methods would probably be appreciated by many readers. The use of the dividers, square and other tools, in the laying off of holes, does not always give the best results, as the chances of error are so numerous that it is frequently impossible to maintain the accuracy required. It is, of course, in the repair shop that these operations are mostly met with; new parts being fitted to old ones, old parts being replaced, etc. Fig. A shows a new shaft being fitted to an old collar, the latter containing the holes previously used. This looks like a very simple job, yet if the hole is drilled out of line with that already in the collar, the insertion of the pin becomes a neat little operation of banging it around several corners until it finally peeps through the other side—a sorry looking pin, indeed.

A good way to avoid all this is to provide a V-block with a hole drilled through the center. It is then a simple matter to turn a piece of stock on the end to fit the hole in the collar and insert this in the hole drilled in the V-block. It will then be obvious that the collar and the shaft will be lined up properly and the drilling of the hole in the shaft will be done with a great degree of accuracy. A reverse condition to that just cited is shown at B, where the new collar requires drilling to fit the hole in the old shaft. The shaft, with the collar on the end, is placed in the V-block and adjusted so that the drill will enter the hole freely. A small parallel is then clamped to the shaft, with its side touching the V-block and the end resting on the drill table. The sleeve is now pushed into position and the shaft clamped down, first noting that the parallel is touching both surfaces as before. In starting a drill on a convex surface it is well to bring the drill lightly to the work until it has sufficient depth to guide it.

A convenient center punch for transferring the centers of holes is shown at C. It is made in three pieces, the punch being made of tool steel. All moving parts are made a sliding fit and the outer ring knurled to facilitate handling. Two small screws serve to keep the part together when not in use.

It is often required to fit a new cover to an old flange, where the latter has blind tapped holes. A case of this kind is shown at D. The old cover not being at hand, the work was set up as shown, a V-block being clamped on end and the flange pushed up against it, then lined up until the drill enters one of the holes. The new cover is now placed on top, clamped, and the hole drilled, a pin pushed into the hole, and the others drilled in the same way.

At E is shown a set up for drilling the holes in the periphery of a collar. Both old and new pieces are bolted to the angle iron and the latter position on the table controlled by two parallels fastened to the table, at right angles. Lateral movement of the angle to obtain the correct position for the new holes is obtained by means of a small cylindrical piece turned to the diameter equalling the center distance of the two collars. This method of drilling holes to conform to others is practically that of jig drilling. One big advantage with this method is that any inaccuracy in the initial piece is duplicated in the new piece, thus assuring a better result than if uniformity had been adhered to. There are very few cases where holes cannot be transferred direct by adopting a few simple principles as here outlined.

The gauge shown at F is one that may be used to good advantage in the locating of a center between two parallel slots or the sides of work. In operation the end pieces are adjusted to fit the slots when the bushing will be automatically centered; a center punch turned to fit the bushing is used to make the center mark.

GENEVA MOVEMENT PROBLEM

By G. Barrett

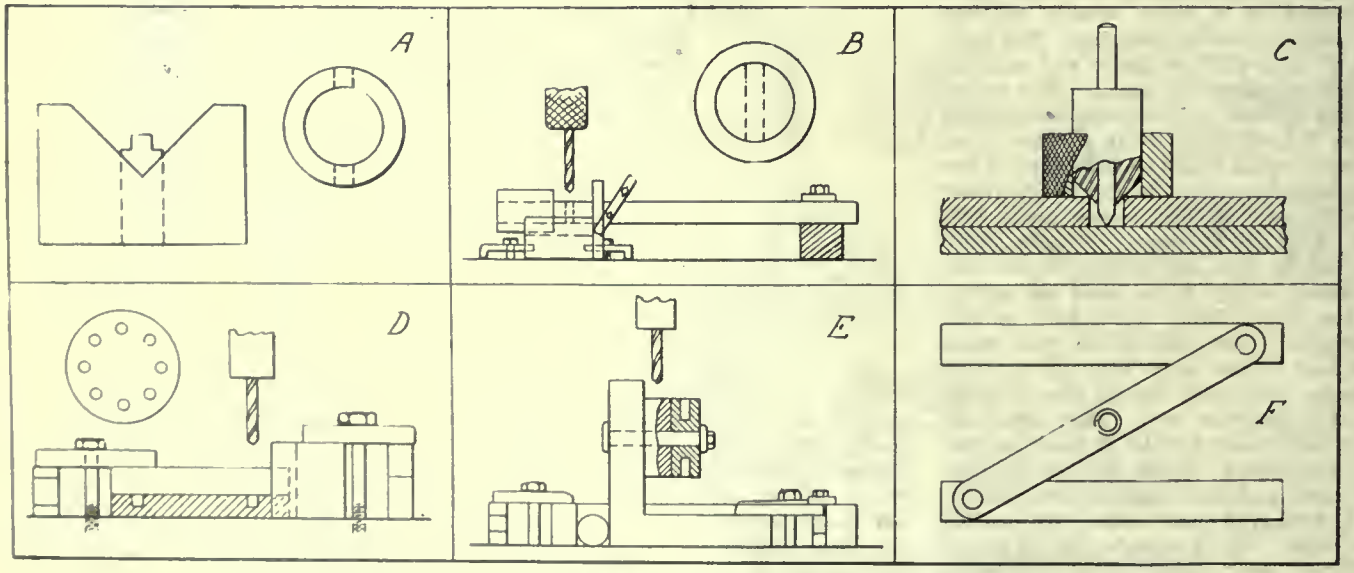
Relative to the Geneva movement problem appearing on page 398 of the October 28th issue, I submit the following as my method of manufacturing this piece. The material used would be cold rolled bar stock of the required diameter. The first operation would be performed in a small turret lathe, using two box tools, one for roughing and one for finishing the boss on the movement 19/64 inch in diameter, drilling the 7/32 inch hole in the center, and parting off to the desired thickness. The box tool, which is of the hollow mill design, is shown at A, Fig. 1. These tools would give good results provided ample chip clearance was allowed for. The output from this operation should be approximately 30 per hour, or about 2 cents apiece.

The next operation would be the milling of the slots. The jig or fixture for this work would be similar to that shown in Fig. 2, which is of simple design, made from machine steel and hardened. The upright portion is bored in the center to fit the boss of the movement which is held to the face by means of the clamp B. As the slot being milled is 7/64 inch wide, I would use a 3/32 inch saw cutter; this would leave a few thousandths for filing. This particular operation would constitute a milling of one of the slots in all of the pieces, and would cost about 40 cents per hundred.

The fixture used on the succeeding operation would be identical with that shown in Fig. 2, but would have a small locating block as indicated at C. This method would eliminate the necessity of having an indexing attachment on the jig, and would be far more accurate, as there would be no working parts to wear and produce errors. Completing this milling of the slots would approximate a cost of 1¼ cents per piece.

We now come to the stage where the 29/64 inch radius would be formed. This would be accomplished in a punch press using a punch and die similar to that shown in Fig. 3. The die is slotted at D to receive the boss of the movement, and also to receive the locating pins E and F. These pins would be placed to bring the movement in the proper position for punching. The punch is cut away in front so that the back portion will act as a guide before the punch part G comes in contact with the work. The cutting face of the punch is ground at an angle of about 8 degrees to provide for proper shear. The cost of this operation would be approximately 40 cents per hundred.

The final operation would be finish filing to gauge. The slots would be filed to fit on the steel projection H, Fig. 4.



SIX HANDY HINTS. READ THE TEXT WHICH EXPLAINS THE STEPS CLEARLY.

The final gauging would be done on the gauge Fig. 4, which is made of a flat piece of steel with a hardened and ground pin to fit the bore of the movement, and another piece I hardened and ground and located in the block at the required center distance from the center pin. This final fitting would also serve to check up all other operations. This concluding operation would be done at a cost of about 8 cents apiece.

DOUBLE PARTING TOOL

By Clyde D. Thorburn

Some time ago we illustrated a double parting tool for use in cutting piston rings from sleeve casting, and the illustration herewith is that of another double tool for the same purpose. This tool was designed so as to have a longer life and would always be standard width between cutters. It is ground only on top of cutting edge, its design allowing the necessary clearances required. Body of tool is made from mild steel forging shaped on all flat surfaces and two grooves sawn in head to receive the high speed circular cutters. The cutters are turned slightly concave to insure continuous clearance and bevel on cutting face to make a clean cut-off.

The top tool is turned ⅛ inch larger in diameter than bottom tool. This is to allow for sufficient strength of metal to hold on the lower ring when parting off upper ring. Six ⅜-inch holes are drilled through the cutters and hole to correspond through jaws being tapped through one side of jaw to take the retaining pin. This allows for the moving of cutters as they are ground back through wear. The tool can be used on the side head of a Bullard vertical or ordinary vertical boring mill. We are using it there and find it a distinct advantage over previous tools.

WELDING OF LOCOMOTIVE FIRE BOXES

Continued from Page 629

Welding Half Door Sheets Riveted to Side Sheets

In preparing to weld half door sheets above or below the doorhole, the sheet should be cut not nearer the doorhole than between the first and second rows of staybolts as shown in Figures 72 and 72A. All the staybolts, except those adjacent to the weld, may be screwed in place. The door sheet should be riveted to the side sheet and mudring before welding, and the weld vee should be formed as shown in Figure 73.

Next weld the flange at 1, Figures 72 and 74, then at a distance of about 10 inches from 1, back weld from 2 to 1, from 3 to 2 and continue to 8. Figure 75 gives details of the end of the weld.

Patches on Cylindrical Shells

Sketches A and B, Figure 80 show how patches should be applied to cylindrical shells and tanks. The base of the triangular patch should run with the circumference of the shell. A weld like that of sketch A should be started at 1 and go to 3, and be allowed to cool. Then from 3 to 5 and cool. Finally from 5 to 1. The weld of sketch B should be run from 1 to 3, and allowed to cool. Then from 3 to 5 and cool, and from 5 to 1.

Locomotive Flues

To weld locomotive flues, first countersink the fluehole about 3-16 in. deep, as shown in Figure 81. Extend the flue to within 1-8 in. of the outer surface of the sheet and 1-16 in. beyond the bottom of the countersinking. Leave out the copper ferrules, and expand the flues just enough to fill the flueholes. Start to weld at the bottom of the hole, and weld around to the top on one side, and then the same way on the other half. Weld the fillet flush with the inside of the flue and the face of the flue sheet. Figure 83 shows the order in which the flues should be welded so that unequal expansion may be allowed for. Weld the row of flues 1, 2, 3 and then 4, 5, 6, then 7, 8, 9 and so on to completion.

Johnny—"Mother, why did you marry my dad?"

Mother—"Johnny, I married your father because he once saved me from drowning."

Johnny—"I'll bet that's why he won't teach me how to swim."

THIS IS HOW MR. BARRETT WOULD HANDLE THE JOB.

DEVELOPMENTS IN SHOP EQUIPMENT

NO. 4 PLAIN MILLING MACHINE

The Ford-Smith Machine Co., Ltd., Hamilton, Canada, have placed on the market a new machine to be known as their No. 4 plain milling machine.

This machine is of new design, and contains various features worthy of special attention. For example, special care has been given to centralized control of all movements of the knee and table, and rapid power is provided in all directions. This makes for speedy production, and the range and coarse feeds are said to be equal to those provided on geared millers.

Various Details

The column is of box section, with heavy wall and bars for supporting the knee and bearings. It is provided with door and shelves for holding necessary tools, etc. The spindle is a crucible steel forging, having a hole through its entire length. The front is threaded to receive a chuck or large cutter head, and this thread is protected by a cap when not in use. The front bearing is tapered, the back bearing parallel, the wear in the latter being adjusted by drawing up a bush which fits solidly into a tapered hole in the column.

The spindle is boxed for a B. & S. standard taper, and front of spindle is slotted, thus providing a positive solid drive. Each arbor support is provided with a wedge key, operated by a ball handle, this locking and locating the arbor support positively in line with the spindle.

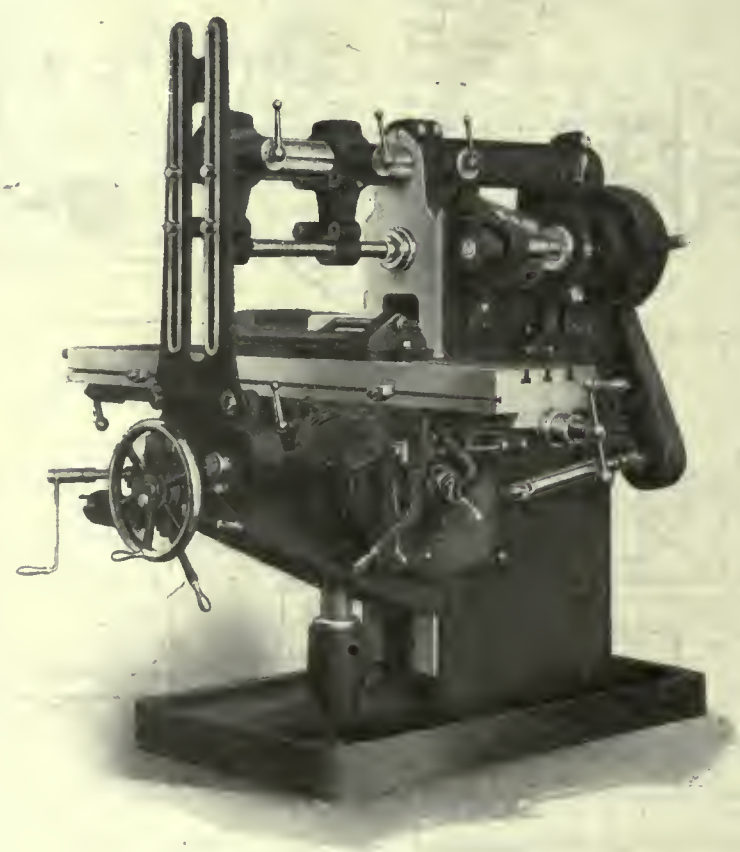
The knee is designed to give maximum rigidity under the bending and twisting stress of the cutter. It is a box casting of the solid top type, being well braced internally with short ribs. There are no holes in top or sides of knee. It is locked on the column by means of a handle located at the front of the knee. A narrow guide with an adjustable taper gib is provided for the saddle slide. The cross screw is located near the centre of the guide, thus giving easy motion to the saddle. The knee has power elevating feed through a telescopic screw with a ball thrust. This avoids the cutting of hole in floor to clear the screw. Graduated collars reading to one thousandth are provided on table, cross, and elevating screws.

The table is of very rugged construction with wide bearing and great depth. It is provided with oiling arrangements from the front, also felt wipers. The feed is autometic in both directions, and has a positive knock out.

The feed box is not carried on the column in the orthodox manner, but is bolted to an extension of the saddle on the knee. This new departure makes possible the arrangement of a dial feed hand wheel, handy to operator at working position in front of knee. Twelve changes of feed are obtained from the dial, which, in conjunction with the coarse feed handle at the front of column. gives twenty-four changes when the back gear is in.

All feed gears are hardened steel, ground in the bore. The feed shafts are also hardened and ground. A cone miller is often handicapped on large face milling work on account of the feed dropping in proportion to spindle speed, this, of course, causing lower production on work which must run at slow spindle speed. To overcome this trouble a feed change is provided next to the spindle. For ordinary work the feed is driven off the feed pinion keyed to the spindle, but when the back gears are engaged, the feed may be driven off the cone pinion which speeds up the whole feed mechanism 3 to 1, or 10.8 to 1, according to the ratio of back gear engaged, thus making possible the very coarse feeds provided. The range of feed is from .096″ per rev. of spindle, to 1.56″ per rev.

The feed reversing mechanism is carried in the feed box on the knee, giving a reverse to all feeds. The rapid power control levers have to be held in position by hand while the rapid power is engaged, making accidental or thoughtless operation impossible. Should the feed run over at any time, a safety trip device prevents any breakage or damage. This machine is said to be the only cone driven machine having rapid power to knee as an integral part of the design. The countershaft is of two-speed friction



GENERAL VIEW OF NO. 4 PLAIN MILLER.

type with self-oiling bearings. Friction clutches are of improved expanding type, carefully balanced, with means for taking up wear, Machine is, of course, supplied with all necessary wrenches, oil pot, cutter arbor, etc. Following are the principal specifications:

Table working surface, 71″ x 14½″; T. slots, three ¾″; Longitudinal traverse, 42″; Cross traverse, 12″; Vertical traverse, 20″; Face of column to brace, 30″; Dia. of spindle in front bearing, 3½″; Size taper hole (B & S), No. 11; Size hole through, 13/16″; Spindle speeds No., 18; Spindle speeds range, 14 to 415 R.P.M.; Overarm dia., 4¾″. Distance centre of arbor to underside overarm, 7¼″; Large cone dia., 13″; Cone belt width, 3½″; Ratio back gear, 3 to 1, 10, 8, to 1; No. of feeds, 24 with back gear in, 12 without back gear in.

Range of feeds per rev. of spindle, .002 to .39″ cross and elevating, .006 to 1.56″ table screw; Rapid power traverse, 12″ per min. elevating, 32″ per min. cross, 130″ per min. table traverse; vise plain, 8½″ wide, 2⅛″ deep, 7″ opening; Countershaft pulleys, 16″ dia., 5″ face; Countershaft speeds, 180 and 220 R.P.M.

BALL BEARING DRILLS

Output, convenience, durabillty. These are the features much to be desired in any machine tool. The Alfred Herbert, Limited, Coventry, England, claim all three for their varied line of ball bearing drill presses. The first of the photographs (see Fig. 1) depicts a form spindle machine with three plain and one geared spindle. All spindles have automatic, self engaging, self releasing feed mechanism. Fig. 2 shows a two spindle plain lever feed machine.

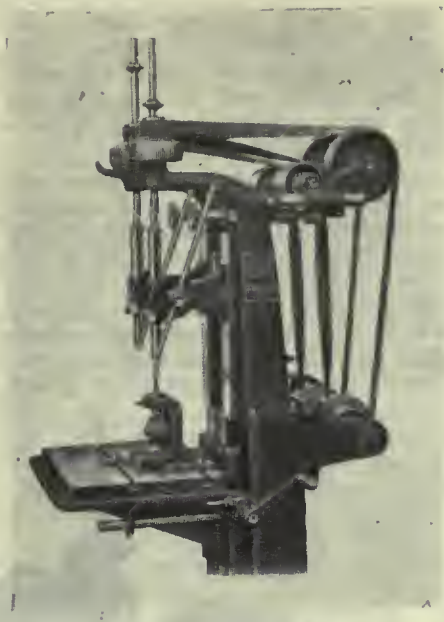


FIG. 2—TWO-SPINDLE PLAIN LEVER FEED MACHINE.

Every bearing in these machines is a ball bearing, and we illustrate a sectional view of the spindle showing the spindle pulley bearing see Fig. 3. The spindle bearing construction, is unique in design and is patented. The only running bearing on the spindle is the one near the bottom of the spindle which takes all journal load, and upward and downward thrust. The reason of the success of this bearing under combined journal load and thrust is that on a vertical drilling spindle the end thrust is always greatly in excess of the side pressure, thus insuring that the load is continuously and equally shared by all the balls, and no ball ever has to sustain more than a very small fraction of the whole load.

The spindle passes through the feed sleeve without touching it, and is provided with a dust cap. The illustration of the spindle pulley clearly shows how the upper end of the spindle passes through but does not touch a fixed bush, the outside of which carries the two annular ball bearings of the spindle pulley. The spindle is splined and is driven by a key and centralized by the part of the pulley which projects above the fixed bush. This construction has proved of high mechanical efficiency, avoids all necessity for "floating" drives or other devices for preventing the spindle from binding in its bearings, and is simple and free from the possibility of faulty adjustment. The spindle is balanced by a flat helical spring acting on the pinion shaft, which eliminates the more common chain and balance weight and works with much less friction.

The self engaging, self releasing, automatic feed feature is worthy of note as it is said to be a great aid to production. The operator merely pulls down the feed lever until the drill touches the works, upon which the machine automatically feeds the drill, stops feeding at the required point, and then instantly withdraws the drill. Three rates of feed are provided with the automatic feature.

Briefly, here are some other points of interest. These machines have a belt system by which six speeds to each spindle are obtained with the belt properly tracked for each speed, the convenience of the belt tensioning arrangement, the exceptional table area, the convenience of the two T slots in the tables, the con-

FIG. 1—FOUR-SPINDLE MACHINE WITH THREE PLAIN AND ONE GEARED SPINDLE.

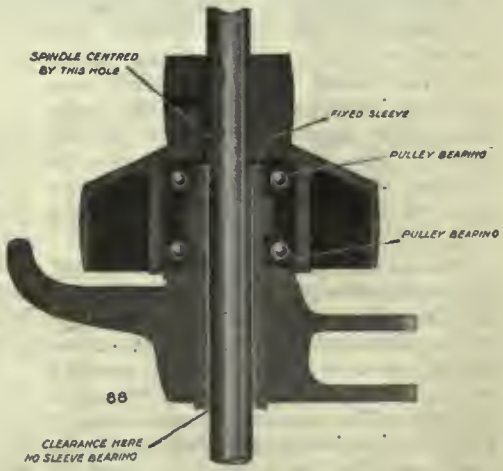

FIG. 3—DETAIL OF SPINDLE PULLEY BEARING.

venience of the elevating and lowering motion to the table by rack and pinion. The general rigidity of the machine is worth notice, also the convenience of the pump and fitting arrangements, which have no easily choked flexible pipe connections.

These drilling machines are supplied in one to four spindles with any combination of spindles, i.e., with plain lever feed spindles, plain spindles with automatic feed, or geared spindles with automatic feeds. The maximum capacity in steel of the plain spindle is one inch, and of the geared spindle one and one-quarter inch. The range of six speeds on the plain spindle is 230, 530, 600, 900, 1,370, and 2,050 r.p.m., and on the geared spindle 77, 147, 170, 194, 321, and 424 r.p.m. This concern have their Canadian office and showroom at 1-3 Jarvis Street, Toronto.

LARGE TRIMMING PRESS

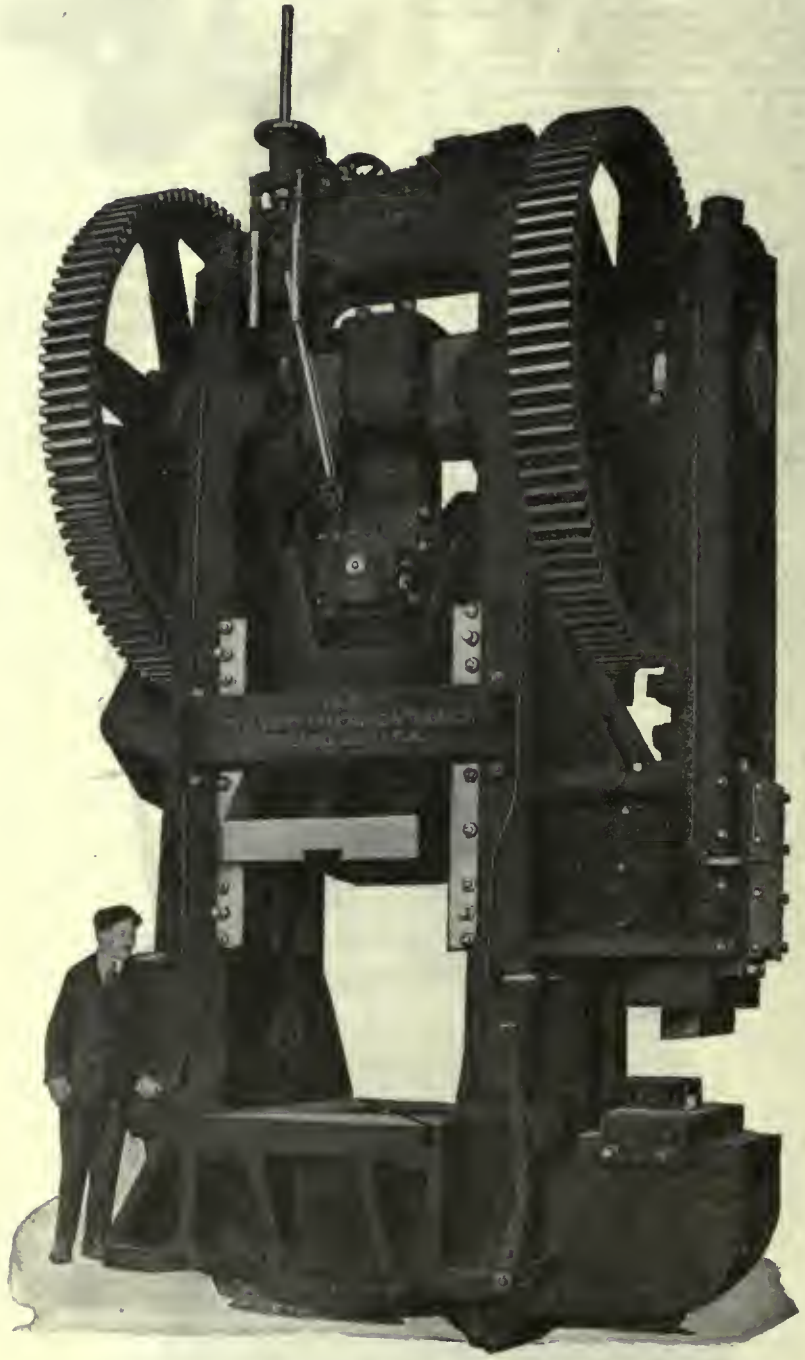
The accompanying photograph illustrates what is said to be the largest single crank trimming press, with side shear, that has ever been built. The press has a number of special features which are worthy of note. The frame is of the four-piece steel tie rod type of construction, which consists of a base, two uprights and a crown, held together by four large steel tie rods which are shrunk into place. These four rods take the stress. The uprights are extra heavy to withstand any lateral stresses which might occur when the slide is unevenly loaded. Presses with this type of construction are capable of economically operating dies for the heaviest kind of work that can be done in presses. The twin gears on the main shaft are an original feature in a trimming press of this character, and it will be noted that the design is such as to make an entirely self-contained machine without any outboard bearings and with the main gears close up to the uprights of the press. The gearing, moreover, is mounted high on the frame and in no way interferes with the operator at the back of the press.

The outside shearing or cutting off slide is particularly massive and substantial. It is operated by an eccentric shaft, which extends through the bearing in an auxiliary housing, secured to the outside slide housing by steel tie rods. The press is controlled by a powerful hand actuated friction clutch which enables the operator to start or stop the machine at any point of the stroke. The slide is raised and lowered to the proper adjustment by a special power driven elevating device. This saves considerable time when changing dies of varying heights. All the main bearings are lubricated from the floor by a centralized forced feed lubricating system. The press is driven by a direct connected 50 H. P. motor mounted on a bracket at the rear of the machine.

This press is specially adapted for trimming crankshafts of twelve cylinder aeroplane engines, and it will readily trim other work of larger dimensions which is forged in 15,000-lb. hammers or even larger.

An idea of the size of the press may be had from the following dimensions: weight about 185,000 lbs.; area of slide flange F. to B. x R. to L. 68 x 40″; area of bed F. to B. x R. to L. 72 x 48″; standard stroke of slide 16″; distance bed to slide stroke down and adjustment up 30″; stroke of outer slide 6″; ratio of gearing 44:1; number of strokes per minute 7″; extreme height over floor 229″; floor space over all F. to B. x R. to L. 137 x 166″.

The above press has been designed and built by the Toledo Machine and Tool Company, Toledo, Ohio.



THIS VIEW GIVES A GOOD IDEA OF THE SIZE OF THE PRESS.

HEAVY DUTY BORING MACHINE

As far back as 1916 the Rockford Drilling Machine Co., Rockford, Ill., became convinced there was a demand for a single purpose heavy duty horizontal drilling and boring machine, which could be highly standardized, and still be flexible enough to meet practically any requirement. The result of this belief is shown in the two photographs herewith. The machine illustrated is one of three built for a large motor works, for boring crank shaft and cam shaft bearings. This machine is provided with two duplicate fixtures mounted on an index-

ing table. The loading station is at the rear of the machine, and the operating station at the front.

As a nucleus, the head of the Rockford vertical heavy duty drilling machine, complete with drive gears, spindle and feed mechanism, was selected. This head can be shortened to give as little as 12-inch spindle travel or increased to give 40-in of travel. In combination with the different spindle designs and multi-spindle drive heads, it gives the means of rotating the bars and tools.

The main drive may be by either motor or countershaft. In the countershaft drive, a three step cone is provided and a Hyatt roller bearing tight and loose pulley countershaft. The motor is directly connected through gears and without the use of flexible couplings or chains. Interchangeable pick off gears are provided for speed changes with both types of drive. Feed changes are four in number and are incorporated in a simple feed box with drive-key. The feeds available are varied to suit the work but are always in geometric ratio with a factor of 1.5. A forward and reverse feed mechanism can also be provided. All bearings on both drive and feed are bronze bushed. The base is of heavy box section, well ribbed and is bolted together in such manner as to facilitate the changes in design without many pattern changes. The feed and drive mechanism are completely mounted on one base section and the fixtures are mounted on the other section.

While one fixture is being unloaded and loaded, and the bars and cutters changed at the loading station, the other fixture is at the operating station and the piece it holds is being bored. When these operations are complete, the operator disconnects the bars from the drive head and steps on the foot treadle which projects through the front side of the base. This treadle pulls the index pin and lifts the table slightly off its bearing on the base and on to a large ball. The table is then rotated 180 degrees, bringing the new job in line with the spindle and the finished job around to the loading station. This method of handling makes the operation almost continuous.

This machine bores two crank shaft bearings 2 9-16 ins. diameter by 2 3-4 ins. and 2 15-16 ins. long and three cam shaft bearings 2 3-16 ins., 1 57-64 ins. and 1 55-64 ins. by 3 1-4 ins., 2 9-16 ins. and 3-4 in. long respectively, simultaneously in aluminum at a cutting speed of two hundred feet per minute and .010 in. feed per revolution of the spindle.

The operations are divided into rough boring, facing and finish boring, a machine being provided for each operation. All these operations with the addition of counter boring, drilling, etc., may be combined on one machine if the production does not warrant more equipment.

Care is taken in designing all fixtures to provide adequate clamping devices of such form that the case will be held firmly but not sprung out of shape. In this particular case, the lower surface of the crank case is clamped against hardened steel plates mounted on a vertical surface. This facilitates changing cutters and keeps the locating surfaces clean. Location of the case is by means of hardened dowels entering reamed holes in the lower surface of the crank case. These dowels are relieved of all cutting strain by means of spring plungers which are locked after the case is in position.

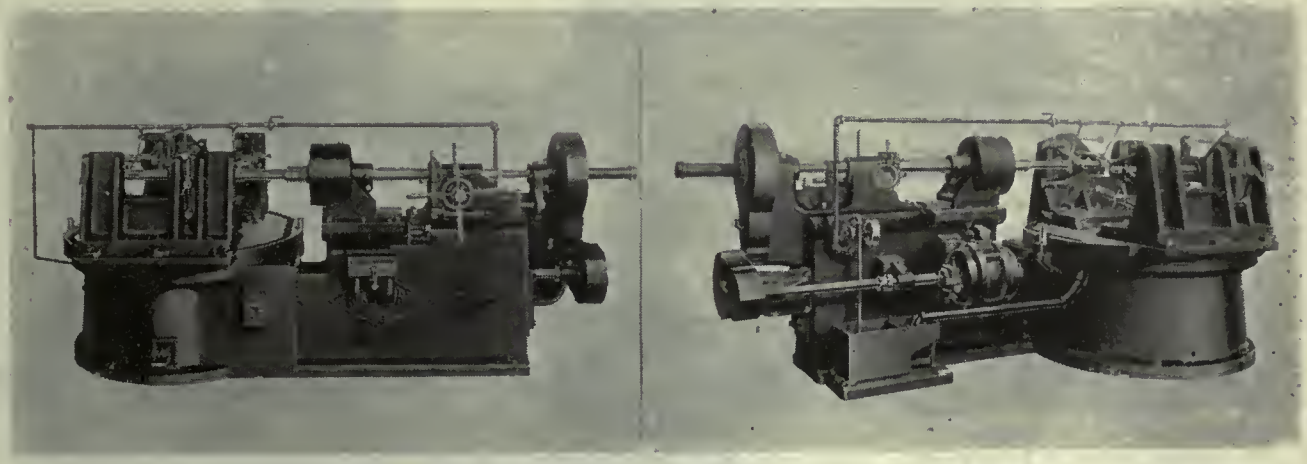
The equipment for the above includes a complete set of Kelly Reamer Co.'s bars and cutters. A floating drive is used between the bars and spindles so that the accuracy of the work depends upon the fixture alone. Liner bushings are provided in all cases so that it will be very easy to maintain alignment of the fixture. The bars are provided with wearing strips which may be packed up and re-ground to keep the bars up to the standard size.

These machines are adaptable to a wide range of work and are easily arranged to take care of holes from 1 inch in diameter in steel to 12 inches in cast iron and aluminum. They are rated at 2 1-2 in. diameter drilling from the solid in steel and have demonstrated their ability to withstand continuous production over a long period of time.

Following is a partial list of work for which these machines have been adapted: crankcase boring for tractors, trucks, and passenger cars; transmission case boring for the same; cylinder boring for tractors; front axle (king pin hole) drilling and reaming; rear axle drilling and boring; gun carriage work (77 m.m. and 150 m.m.); centering of large forgings; milling pads on crankcases; facing and counterboring bearings in crank cases and for double end drilling.

DUPLEX TURNING AND BORING MILL

An improved type of duplex turning and boring mill is shown in the accompanying illustration. This machine is an example of the new range of turning and boring mills being manufactured by Webster & Bennett Ltd., Coventry, England.



GENERAL VIEW OF THE MACHINE, SHOWING FRONT AND REAR VIEWS.

It is a duplex machine with 42-inch diameter work tables, each forming a separately driven and operated unit. The other sizes of machine, which constitute the full range, are 20 and 30-inch duplex machines, and a 30-inch single machine. The machines in each case are built on the unit principle. The machine illustrated embodies some new and distinctive features making for high productivity with a minimum expenditure of labor. All controls are centralized, rapid power traverse is applied to all slide movements, and special provision is made whereby the turret heads may be quickly and easily rotated irrespective of lack of balance, due to heavy overhanging tools.

The distribution of metal to give maximum strength has received special attention, and the main castings, such as the base, columns, cross slides, saddles and turret slides, are heavily ribbed to enable them to withstand the heaviest duties to

which, by recent advances in cutting tools, the machines will be submitted.

Evidence of the consideration in this direction is seen in the method employed in mounting the turret-head cross slide, which incorporates the narrow guide principle. It will be noted that the cross slide is supported by square and V-shaped gibs at the bottom of the slide. This design also gives a direct thrust to the cross feed screw, which is located in the lower portion of the slide way.

The machine is entirely self-contained, power being supplied through all-geared speed boxes, driven by two separate motors—one to each unit. These are mounted on platforms seen immediately behind the turret heads. Correct tension is maintained on the belt by arranging the platforms on a rocker, and by means of screw-operating mechanism the platform and the motor contained thereon may be tilted over until the desired belt tension is obtained. The gear boxes are of the sliding gear type, and give a wide range of table speeds, rising in geometrical progression. The speeds may be quickly varied by simple lever movements, and in order to prevent gear breakages through careless operating the friction driving clutch becomes disengaged before the sliding members can be moved. The left-hand table in the duplex machines is equipped with a reversing motion, which enables the operator, when turning and surfacing, to work with the tools adjacent to the tool control levers. For drilling and boring or reaming, standard tools are used and the table runs in the reverse direction, whereby a heavy outlay in left-hand tools is avoided. The feed changes are effected by hand levers through the different combination of sliding gears contained in boxes at the foot of the columns.

On the change levers are numbered plates which indicate at any time the actual feed engaged. All the driving gears are made of steel or phosphor bronze, and those in the speed box are of chrome nickel steel, heat-treated for maximum strength. A special form of tooth is used throughout in these gears which, together with the high tensile steel of which they are made, makes practicable the use of fine pitches and small diameters, thus strength is maintained and high peripheral speeds are eliminated. Lubrication to the gear boxes is effected by means of filtered oil through siphon tubes, and oil emerging at the end of the bearings is automatically returned into the box.

Control Features

The levers seen at the side of each table control all speed changes. The feed changes are made by means of levers on the top of the feed box, the direction of their application, however, i.e. to vertical or longitudinal feeding, is determined by the lever directly under handwheel at right hand side of photograph. Rapid or slow power traverse movement, in either direction, for convenience in setting the tool to the work, is actuated by means of the lever directly under the previous lever spoken of. By the above control arrangement, the operator seldom requires to move more than a few inches from the working position. Positive feeds may be instantly thrown out of engagement and rapid power traverse put into gear, thus enabling the turret to be quickly brought into any desired position, with the smallest expenditure of labor.

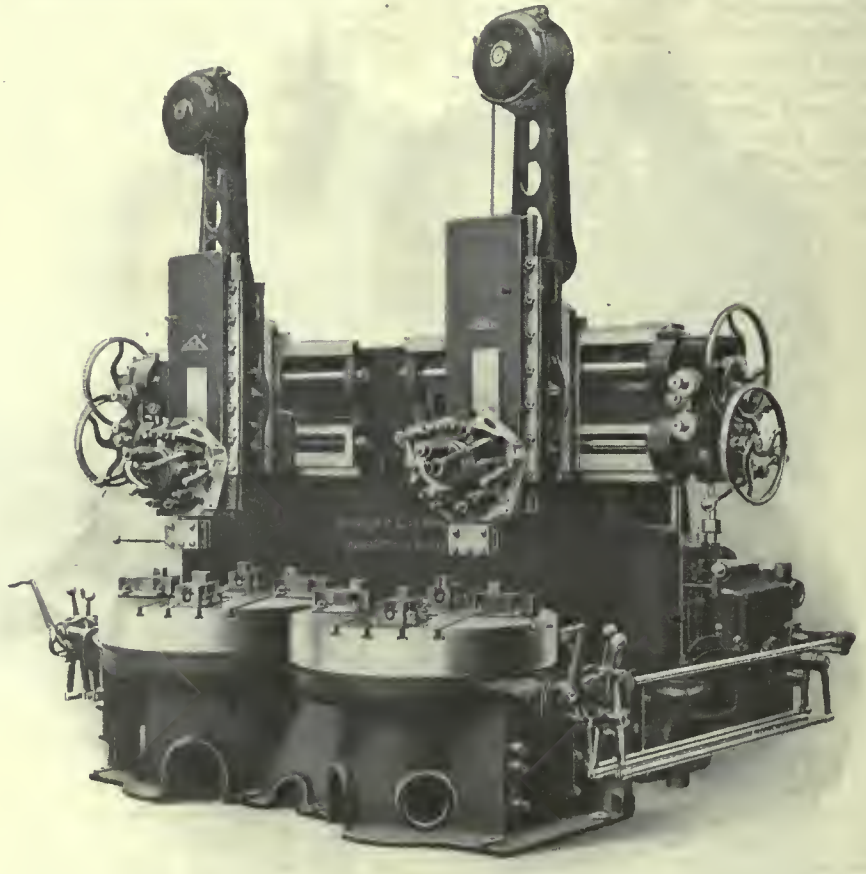
The latter lever has a compound movement, and actuates the positive feeds or the rapid power traverse motions in either direction. To operate the longitudinal traverse, the first lever is raised, then by elevating or depressing the second lever the slow or fast feeds are engaged. By moving this lever either to the right or left, the saddle is operated in a corresponding direction.

An automatic trip device is embodied in the feed motion, whereby the feed may be automatically tripped at any point.

Arrangement of the Turret Head

Another feature of this machine is the arrangement of the turret heads. These, as will be noted, can be set over to operate at an angle, and are counterbalanced by means of a powerful spring, actuating through wire cable over a fusee, thus maintaining a constant pull against the weight of the slides and tools at all times and in all positions. The arrangement is safe and compact and in no way restricts the movements of the operator. Within certain limits the displacement of the centre of gravity of a turret head, due as frequently happens to an unbalanced arrangement of the tools, is no disadvantage to the operator and no time is lost in bringing the turret into any required position. Beyond this a rotating mechanism becomes essential, both for the safety of the operator and as a waste time eliminator. On the 42-inch machine shown, arrangements are provided to neutralize the effects of overhang or heavy boring bars, tool holders and so forth, and the turret may be very easily rotated without the slightest risk.

To make a turret movement, it is first unclamped by raising the lever shown (which unlocks the turret from the slide), then by raising the lever on the left side of the turret, the indexing plunger in the turret is withdrawn, and by one revolution of the arm directly below this latter lever (which is geared by a pinion and internal gear to the turret) the next tool station is brought into the cutting position, after which it is locked by the two levers as before.



GENERAL APPEARANCE OF DUPLEX BORING MILL EQUIPPED WITH 42 INCH DIAMETER TABLES.

VARIETY SAW BENCH

The Oliver Machinery Co., Grand Rapids, Michigan, have placed on the market a new variety of saw bench. This machine is made in either motor-driven or belt-driven style. The machine is designed for the production of variety

wood work, wood patterns, furniture, automobile bodies, agricultural implements, etc. It will do ripping, cross cutting, and will cut mitres. In other words it is a wide range variety saw.

The construction is rugged throughout and all necessary attachments, such as mitre cut-off gauge, etc., are provided. Two types of tables can be furnished, plain and universal. The latter has a 15-inch rolling section to the left of saw, which rolls on ball bearing ways having vertical adjustment for alignment and wear. The rolling table can be moved four inches from saw, this permitting the use of dado saws and special heads. This table also permits doing accurate cross cutting, mitreing and grooving.

The table has a tilting device which consists of a hand wheel, worm and gear device, housed in a dust-proof casing attached to yoke with connecting link to table. This makes a positive and self-locking arrangement as a clamp screw is provided for positive clamping at any tilted position. The table can be tilted to 45 degrees to the left.

It has also a vertical adjustment, and if desired a plain table can be furnished. The universal table, however, is shown in the illustration.

It will be noted from Fig. 2 that the motor drive is not an afterthought, but has been built right into the machine; 5 horsepower is required when belt-driven, 3 to 4 horsepower when direct-motor driven. The motor on arbor machine is for 2 or 3 phase, 60 cycle alternating current. For other currents a standard motor running at about 1,800 r.p.m. is mounted on a sub base bolted directly to the main driving belt, thus eliminating the necessity of a countershaft. Motor pulley and belt are thoroughly guarded by suitable guard.

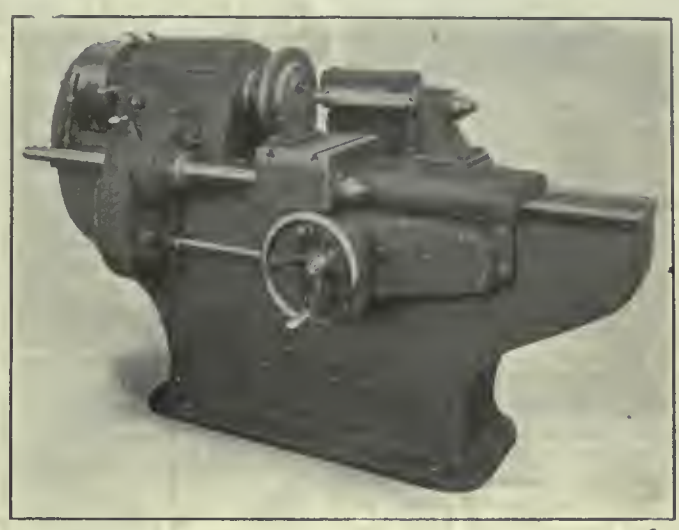
The saw arbor operates on ball bearings, and bearings are encased so completely that no dirt can come in contact with them. The arbor bearings are mounted in a one-piece rigidly constructed housing which is bolted and tongued to frame of machine. This housing is interchangeable as a unit with the motor head arbor when direct mounted motor is desired.

AUTOMATIC TURNING MACHINE

The machine depicted in Fig. 1 represents an entirely new development, manufactured by Thos. Ryder & Son, Ltd., Turner Bridge Works, Bolton, England. It is used for the turning of piston rings, and in fact is adapted specially to all motor manufacturing plants.

With the exception of checking the work, the machine is entirely automatic in action, and will simultaneously turn, bore, and part off bush castings into rings. Concentric or eccentric rings can be produced with equal facility. The machine can also be arranged to turn, the outside diameter, and simultaneously form the ring and oil grooves in piston castings. In such cases the piston is located on a spigot bar, controlled by a hand wheel at the rear end of the main spindle. As the action of this machine is automatic, one operator can attend to a battery of machines, thus effecting a considerable saving.

When producing piston rings, the bush casting is secured to a face plate fixture. The machine is started and on engaging the feed the operation proceeds as follows. Boring tools carried in a bar mounted in the saddle, and turning tools, mounted in the front tool post, commence cutting simultaneously. Next the parting tools, which are carried in a holder mounted on a cross slide at back of bed, begin to part off the rings one by one.

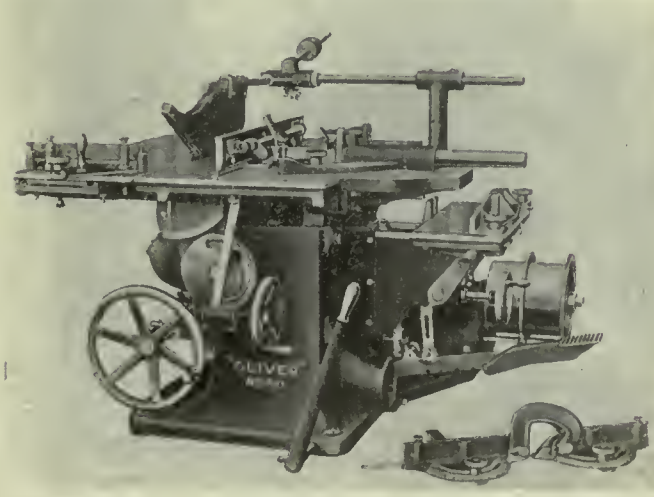


GENERAL APPEARANCE OF AUTOMATIC TURNING MACHINE.

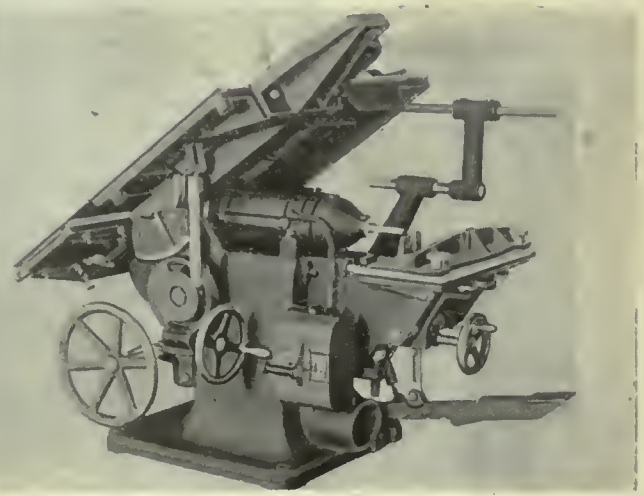
Operations continue until the turning and boring is completed, when the tools automatically stop.

The parting tools continue until the last few rings are cut off, and they also automatically stop. The machinery time for a normal 4-inch diameter ring is one minute.

The machine is of very rigid construction, and work produced from it is very uniform in character. The main frame is of a one piece box section and extends completely to the ground. Chutes are arranged to deposit the turnings away from the tools, slides, and moving parts. The latter are enclosed and protected from dust.



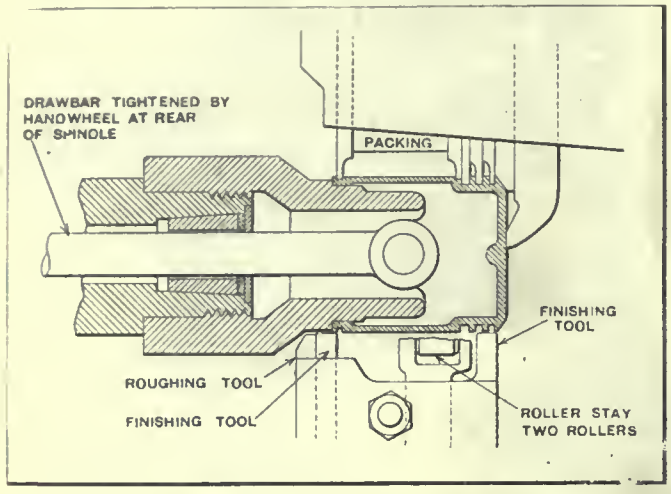
VIEW OF MACHINE WITH TABLE IN HORIZONTAL POSITION.



MACHINE WITH TABLE IN TILTED POSITION.

The drive is by fast and loose pulleys, through a geared head, giving a speed range between the ratios of 2 to 1. This allows for maximum cutting speeds. The main spindle runs in bearings of the firm's special cone-cum-ball bearing type, and splash lubrication is employed throughout. The slides carrying the turning, boring and parting tools are arranged with automatic feed and trip motions which are controlled by one handle only. When a complete cycle of operations is completed, one hand wheel winds the slides back to the original position, each slide keeping in register with the other automatically. The boring bar, as already mentioned, is carried on the saddle, where it is supported in a strong steady rest, and a pilot bush in the spindle nose engages the opposite end, thus ensuring great rigidity. Three boring tools are contained in the bar, which are of large section steel, sufficient to carry away heat. The foremost of these boring tools are circularly ground behind the cutting edge, and so act as effective following stays to the work.

When dealing with pistons, these are previously faced up and recessed at the bottom end, to act as a register on the spigot face plate of machine. The arrangement is shown at Fig. 2. The spigot face plate, which is open at the sides to admit the gudgeon pin bosses as shown, is screwed on to the spindle nose, the bore of the latter being utilized to carry a support bush for the draw back bolt. It will be noticed that the outside roughing and finishing tools are followed by two roller steadies, these withstanding the thrust of the grooving and heading tools carried in the back slide. In the case of pistons with a skirt of full diameter, the steadies traverse out of the way as the sliding proceeds, allowing the finish-sizing tools to follow for sizing the top bands.



ARRANGEMENT WHEN DEALING WITH PISTONS.

The maximum capacity of the machine is to turn pot castings up to 10 inches in length, and outside diameter of 8 3-16 ins. The maximum size of inside bore is 2 1-8 ins. Production times taken from actual practice have shown that pistons 4 1-4 inches diameter, 4 3-4 inches long, have been produced in 8 1-2 minutes each. It is said that one boy can feed three machines, owing to this machine's automatic action.

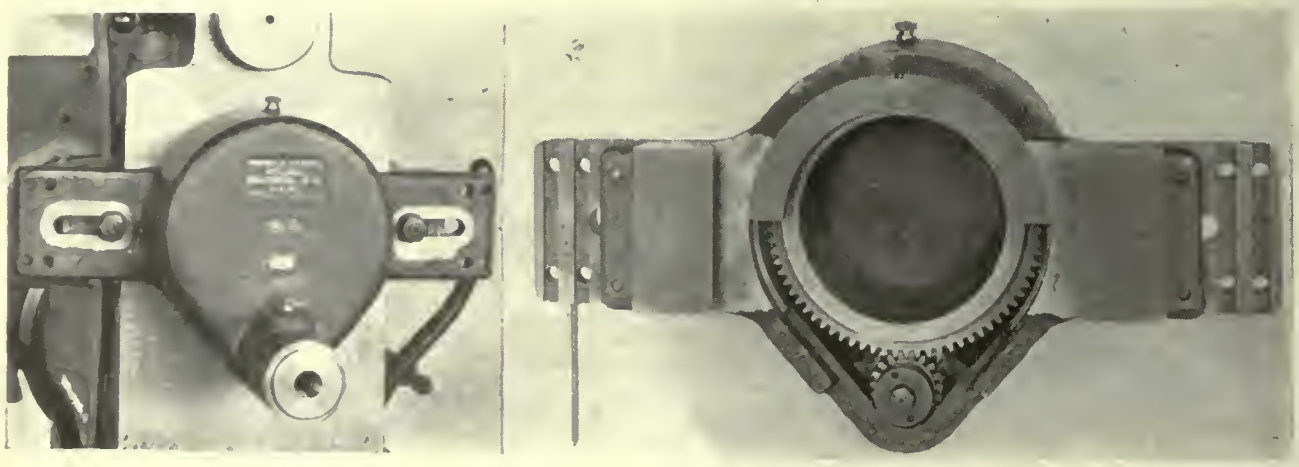
HIGH SPEED MILLING ATTACHMENT

The accompanying illustrations show a new design high speed milling attachment made by the Brown & Sharpe Mfg. Co., Providence, R.I., for use on milling machines of their manufacture. As will be noted the mechanism is simple in construction and easily attached, no fixtures being required. The bracket and spindle support is a one-piece casting of substantial construction, so designed to protect the mechanism from dirt and injury.

The attachment is built in two sizes, the No. 1 for the smaller machines, and the No. 2 for the larger machines. The No. 2 size is adaptable by means of adjustable gib stops to the larger machines, having columns with different width of face, thus eliminating the necessity of a separate attachment for each different size of column on machine.

The positive means of locating the attachment is worth noting. To assure a positive vertical position, the attachment is provided with a locating segment which rests upon the spindle box of the machine. This spindle box projects beyond the face of the column and acts as a centering guide. The horizontal position is determined by first tightening the gib on the right-hand side of the attachment, thereby locating the attachment. The gib on the left-hand side securely clamps the attachment to the face of the column. This affords a large bearing surface, insuring rigidity and making the attachment practically an integral part of the machine.

Particular attention has been given to the drive that it may be positive, though simple, the only gearing being the large ring gear that fits on the taper nose spindle of the machine and the pinion on the attachment spindle. The large gear is made with an internal taper, ground to fit on the taper nose of the machine spindle and is held in position by the regular cutter driver. This gear is made of machinery steel and left soft to insure a smooth drive and eliminate chatter, also the objectionable "ring"



GENERAL APPEARANCE, AND DETAIL VIEW OF HIGH-SPEED MILLING ATTACHMENT.

often produced by hardened gears at high speed. On the No. 2 attachment the pinion is heat treated and keyed to the attachment spindle, while on the No. 1 attachment the teeth of the pinion are cut directly on the spindle.

The spindle is hardened and ground and runs in a long phosphor bronze bearing, the bearing being tapered so that wear is taken up by tightening an adjustment nut, thereby forcing the spindle into the taper. Once having adjusted the spindle a small set screw securely clamps the adjusting nut in position. End thrust is taken by hardened steel and babbit washers located directly behind the shoulder on the front end of the spindle. The front end of the spindle has a taper hole to receive cutters, the smaller attachment having a No. 7 taper hole and the larger one a No. 9 taper hole. Oiling of the spindle bearing is effectively taken care of by means of an oil pocket on the front of the attachment containing wool which insures a constant and even distribution of the oil at all times.

The cutter is held in position by the taper in the spindle and is driven by the tenon. Cutters are readily removed by a releasing bolt which provides a positive means of ejection. This bolt is a part of the attachment and remains in the spindle.

CONCENTRIC CHUCKING

The importance of the chuck as a lathe accessory is too often imperfectly appreciated. The chuck is an indispensable link which connects the work to the source of power and it is obvious that the selection of an efficient chuck is of the greatest importance — otherwise one may have a costly and productive lathe stultified by its inefficiency. The desirable features of a chuck can be summarized as follows: Gripping power, strength, durability and adaptability.

The Coventry concentric chuck, illustrated, made by Alfred Herbert, Ltd., England, is said to embody all these features. Fig. 1 illustrates the chuck with one sector plate and jaw slide removed and from this, the principle of operation can be followed.

The work-gripping jaws are attached to radial jaw slides by square-headed collar screws, engaging nuts which slide in "tee" slots in the jaw slides. Both the base of the jaws and the front face of the jaw slides have fine pitch serrations which engage each other and positively prevent relative movement. The jaw slides are of "tee" section and are held in place by sector plates which fit inside the rim of the chuck body. The jaw slides are moved in and out by a scroll which is rotated through gearing. The scroll has three eccentric grooves in its face, each groove carrying a sliding block which pivots on the cylindrical portion on the jaw slide. The eccentric grooves are portions of a circle, and the sliding blocks are therefore in contact over the whole of the wearing surfaces, a result which is obtainable with spiral scrolls. Dimensioned circles on the face of the chuck facilitate the setting of the jaws.

The exceptional gripping power claimed by makers for this chuck is obtained by the high ratio of gearing used and the efficient design of scroll. The chuck is said to have exceptional strength, and on this point it is interesting to note the claim made by makers "that no Coventry chuck body has ever broken in use, and no body returned to them broken from any cause whatever."

Durability of this chuck is claimed by the makers on the grounds that all the component parts are of the highest class of material, and the refinements in design are such as to prevent rapid wear.

FIG. 1—THE CHUCK WITH ONE SECTOR PLATE AND JAW SLIDE REMOVED.

The makers' claim for adaptability is well illustrated in the accompanying illustrations, Figs. 2 and 3, showing respectively the chuck holding a gas engine cam, illustrating the convenience for gripping irregular or eccentric work, and a back axle casing, an example of the ease with which jaws can be applied for holding objects of irregular form. In this case the jaws shown are exceptionally long, two projecting 5 inches from the face of the chuck and the third 3 1-2 inches. They are shaped to suit the form of the work and arranged so that a five point grip is obtained, making it impossible for the work to rock. This concern carries a stock of soft jaws which customers can conveniently shape to their requirements.

The Coventry concentric chuck is made in six sizes, 9-inch, 12-inch, 15-inch, 18-inch, 21-inch and 25-inch. We have received from the Canadian office of Messrs. Herbert, Ltd., 1-3 Jarvis Street, Toronto, a copy of their booklet entitled "Concentric Chucking" which is something out of the ordinary in this line. Those interested in the question of chucks and chucking fixtures, can obtain a copy upon request.

The Land of Achievement

WHEN one reads the phrase "The Land of Achievement" in a publication issued in New York, it would require no great stretch of imagination to surmise that United States was referred to. In this case it is not. "The Land of Achievement" is Canada, and the publication comes out under the auspices of the Bankers' Trust Company:

"As an evidence of Canada's phenomenal development the latest available figures indicate that the Dominion in relation to nine other industrial countries now stands first in area, second in potential water power, third in total railway mileage, fifth in total exports, sixth in pig iron production, total exports and foreign trade and eighth in population."

Canadians too often get the idea that other countries have a supply of super-men, while at home we have been served with a very average sort. After reviewing Canadian history since 1867, and paying a remarkably fine tribute to Canada's war record, the Bankers' Trust Company refers as follows to the men of Canada who have made this country what it is to-day:

"Needless to say, such a record of achievement as is afforded by the history of Canada during the fifty odd years which have elapsed since 'Dominion Day,' 1867, is not due to chance. Canada has been fortunate during this period in having in political life and in business a group of able, resourceful, morally strong, patriotic men who were not alone capable in action, but capable in leadership. They could not have achieved if there had not been working with them a splendid body of intelligent, determined and resourceful citizenry, men and women of moral force and courage, such as a new country alone seems to develop."

There is need right now in Canada for a decent appreciation of our own people, of our own institutions, resources and possibilities.

In our efforts to go into the markets of the world we need the confidence that comes from a knowledge that we CAN do things in this country.

We need to have developed in our national mind—and we must have a national mind—the idea that we have taken our place among the nations of the world.

Canada is suffering now because her own people simply assent to many of these things. They have never been seized by them, nor have they taken any of the inspiration in to board with them, either in their homes or in their business.

It is well that some enterprising outsider should now and then send out the fact that CANADA IS.

The way in which American settlers are coming to this country with their effects and their cash and the number of American firms already established here and coming over in 1921 is evidence that they have a lot of real dollars and cents faith in the future of this country. Were there any doubt in the matter, these shrewd people would not be staking millions of dollars in property and building here.

Get it, friend, get it. You are living in a real country, and if you are not plowing your field here, someone from the outside is going to see the chance and come in and ultimately reap the harvest.

No Sense of Responsibility

ONE of the lamentable traits that keeps coming to the surface in our industrial life is a lack of sense of individual responsibility for acts done in a collective way.

To illustrate:—A few days ago some forty boys, from 15 to 18 years of age, went on strike at the plant of the Canada Car and Foundry Co., at Fort William, because they were refused an increase from $5 and $5.50 per day to a schedule that would bring them $7 per day.

They promptly walked out, and as a result four hundred men in the plant were forced to quit work. These four hundred had no grievance with the firm, yet they were made idle because forty youngsters thought they could run the works.

It is not likely that any one of those forty boys would care to face those four hundred men and assume responsibility for forcing them out of work, and yet that is exactly what each one did.

The theory, too widely accepted, that there is no individual responsibility for acts done collectively, is a vicious thing, and yet it is surprising the number of people in the industrial world who cling tenaciously to it.

With stores shouting half-price sales and New York funds dangling around 18 per cent., a person has to have a pretty fair education to reckon what his week's pay is really worth.

Doctors in Paris believe that the skin may be so developed that it may perform the function of eyes. Thus will preference be given to the man who sprouts an eye in the back of his neck when a foreman is wanted for a gang of day workers.

The death of Horace E. Dodge following, within a few months the passing of his brother John F., removes from the mechanical world two brothers who started in a small way, faced the vicissitudes of business and conquered. The father of these boys was the owner of a small machine shop, in which the lads learned their trade and undoubtedly learned it well. They made typesetting machines, then bicycles. Following this they turned to automobile parts and then to the finished article, until to-day their plant covers over 100 acres of floor space.

TWO HOMELY LITTLE SERMONS FOR NEW YEAR

Of Course We Don't Refer to You

WERE someone to come around and suggest you were a knocker it may be that you would look highbrow and announce that you did not understand. Well, we'll tell you. Knocker is a pretty fair term—has some strength in it, and is part of the direct action vocabulary that is coming in every-day use when people want to say something when they speak.

Knocker means complainer, whiner, joy-killer, pessimist—a combination of all these things.

In high-up circles they call him a critic, or in a more high-up a critique. In other ultra-pink atmospheres he's labelled a connoisseur. But in honest-to-goodness language he's a knocker just the same.

If he agitates, he never seems to head his movement in the right direction. He uses up his energy to bust up things that his poor little fists could never construct again.

Then there's the different types. There's the chap who can't be chalked up as a noisy knocker. He doesn't exactly set to and heave the mallet in any particular direction.

But he does it in another way. If there's anything in the shop looking toward bettering conditions or securing better results, this bird does not get out on the steps and tell the sun what he thinks of it, neither does he call the boss on the 'phone at his house to tell him the dice are loaded and he won't play.

He's just a lukewarm oyster and about as palatable as a mouthful of soap.

He whispers to his neighbor in the shop, and his whisper puts the spike in any enthusiasm there might be in his corner of the works.

Perhaps he does not intend to be a brakesman on the train of progress, but he's certainly not tossing any fuel into the engine.

This chap is apt to be a poor prune at home. He's a mighty poor source of inspiration for the little woman who fell for his courtship guff, and as a father he's a blank for the children to copy. It would be the part of wisdom for Kith and Kin to forget him until he sprouts a little human enthusiasm and lets the shrub have a chance to grow a bit.

Say, chap, if you want a real tip and one that won't cost you the spending of one red cent—here 'tis—get enthusiastic.

Get in behind something worth while in the plant, in your community or at your own home. Put that little old hammer out on the porch where someone is sure to steal it and bear it away. There always will be some knockers, but for goodness sake don't get mixed up in the scramble for the available supply of hammers.

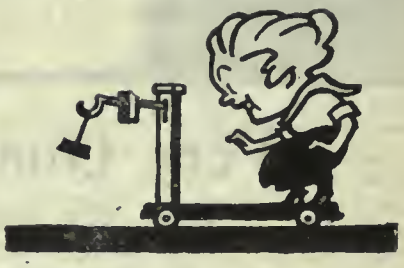
Just a few months ago the man around selling steel was grabbed as soon as he came on the premises and rushed into the combined hospitality of the general manager, the purchasing agent and the superintendent. Today he sits on the bench and waits his turn.

In November, United States settlers entering Canada brought with them $17,519,033 in money and settlers' effects. There might well be a tear trickling down Uncle Sam's cheek as he waved farewell to this delegation.

Better Weigh in Now and Then

THE man whose job it was to clean out the premises of a big publishing house was making his rounds the other night carrying out the scrap paper accumulation of the day.

In one department he came to a big paper container that was so full that much had tumbled off on the floor. That basket looked for all the world as though it had done a good day's work.



It looked as though it had collected a tremendous pile of paper, so much in fact that it was absolutely unable to have another piece tossed at it or near it.

It had the premises around it all mussed up as though to bear witness to the fact that it was an overworked basket.

When the janitor came along he simply looked at it and grunted, and there wasn't even the suggestion of pity in the grunt.

He didn't even say that he'd have to get another basket to stand alongside of the one that seemed so overworked—nor did he say that this basket should only work a few hours and then be let off for the rest of the day.

Not a bit of it. He simply put his big, substantial foot in the basket and jammed that seeming overcrowded load into a little heap down at the bottom.

Then he gave the basket a shot and started it down the hall toward the baling machine.

Say, when that basket was all puffed up with scrap paper and wind and space, you might have been certain it would have made the baler puff to get away with the load. In the end all that frothy load made only a very small little filler in the corner of the baler of paper that was shipped out the next morning.

Did you ever run into any of those big, loose, puffed-up, overworked baskets in the shape of men?

Of course we don't mean you, but of course you know some person else that fits into this story like a fat woman into the average street car seat.

Always puffing around, looking wise, telling the world of the amount of overwork that is heaped on them, posing for the spotter who searches for the super-man, always keen to admit the boss doesn't bulge their pay envelope in keeping with their real weight in mental gold.

You know the rest. Some day they go up against the real thing. Some crisis or lesser event comes along and puts the foot and the pressure on them. They give and they quash, and they crumple up to next to nothing. When they are put in the baler there's not much left. When the wind and the froth and the boast are punctured there's mighty little left.

Better step up on the scales now and then to find out just how much is real and how much is just filling and padding.

The removal of the luxury tax leaves automobile dealers in a peculiar position. They have paid it to the makers and cannot collect it from the customer. If the Government refunds the amount it will defeat the aim of the tax. It goes to show that all matters of taxation and of tariff should be made as stable as possible in order that the business world may have a chance to study them and adjust their affairs accordingly.

MARKET DEVELOPMENTS

Very Quiet Period in all the Markets

Steel Mills Are Down For Holidays, and the Independents May Cut Wages Before They Open Again—Corporation Mills Still Well Employed—Toronto and Montreal Doing Little Trading

THE end of the year finds the machine tool trade quiet in all departments. New York reports more inquiries, but no sales. Toronto and Montreal have somewhat the same experience and look for improvements early in the year.

The steel market is in the same position. Values are easing off a little more, bar material, both iron and steel, being marked down by fractions this week. An interesting situation is developing in the steel rolling district of United States. Most of the independent mills are down for the holiday week and it may be they are down because they have no orders to go on with. Will they reopen at the same wage scale, or will this be the chance to make a reduction?

Several of the independent companies have already announced reductions as high as twenty per cent., and they are working under these conditions now. The Corporation, on the other hand, with its books well filled with tonnage, is not likely to make any move in this direction for the present.

Talk of there being reduction made in steel prices has little sympathy now. It may be that the independents will announce their affirmation of the Corporation schedule. All the large mills have made money in recent months and are not in a position where they have to operate regardless of profit or loss. This being the case it seems unlikely that a runaway steel market can develop.

The scrap metal market ends the year in the dumps. There is nothing in sight to show where any betterment will come from. Even at the low levels quoted, nothing is being traded, and foundries and steel mills refuse to stock up, although it would be to their advantage to do so in some lines at least, as any sort of a buying movement will be sure to have the effect of stiffening prices.

LITTLE BUSINESS IS DONE IN MONTREAL AT THE YEAR'S END

Special to CANADIAN MACHINERY.

MONTREAL, Que., Dec. 30th. — The closing days of the year emphasize the dullness that has been more or less pronounced in many lines of activity during the past several weeks. The crowning event of the period of quiet trading has been the present holiday season, bringing forth an almost total absence of interest in all branches apart from that of retail domestic business. The closing of many industrial plants and the general tendency to shorter work days on the part of those factories continuing operations has still further added to the lull that has settled over many of the country's activities.

Plate and Sheet Prices Revised

There is little to feature trading in steel commodities. Buying is almost entirely confined to essential requirements, and the general trend to inactivity or curtailed operations in various lines of industry, only emphasizes the attitude of buyers. It may be truly said that this does not represent a healthy condition, but it is undoubtedly the reaction consequent on the abnormal state of world trade during the period of the war and the two succeeding years. As one dealer stated—"it is not that industry is in a poor state of health, but rather that it has come to the point where the war paint must be washed off and replaced by more appropriate clothing suitable to the needs of the changed conditions."

"We are passing through a period," continued the dealer, "when we usually expect to experience a falling off of inquiry and demand, but there is no denying the fact that the present is more than ordinarily quiet, and this must be laid to the imperative need that is everywhere evident for establishing a firmer foundation upon which to build the industrial trade of the future, and the coming year in particular. We are more than hopeful that the early spring will prove the time for the laying of the corner stone of the redesigned business structure."

Local steel trading is at low tide this week, due to combined circumstances; holidays and festive season has diverted interest to domestic activities, and more than seasonable slackness in many plants and factories has added to the uncertainty that nearly always influences consumers towards a non-buying policy. Dealers here anticipate a few weeks of quiet buying, but will not commit themselves further. Base quotations on iron and steel bars, from Montreal warehouses, have been revised downwards, the price now being 4½ cents, a decline of ½ cent per pound. Prices on plates are likewise lower, ¼ inch and up being quoted at 5 cents, and 3-16 inch at 5½ cents per pound. Black and blue annealed are easier, showing a drop of ¾ cent per pound, 28 gauge black being listed at $8.50 and blue annealed No. 10 are quoted at $7 per hundred. Quotations on Premier No. 28 are now 10 cents and on 10¾ oz. the price is 10½ cents, a decline of 1½ and one cent respectively.

Machinery Need Is Evident

The past week has been more than usually quiet in machine tool circles.

The curtailed activity of many manufacturing plants has acted as a barometer to the purchasing departments, and in many instances the buying of equipment has been deferred to a more favorable time, or at least until the resumption of activity necessitates the installation of the additional tools, or the replacement of others. Inquiries coming in to the dealers would indicate that consumers and users on many lines of machinery would be in the market if they could assure themselves of an early return of industrial enterprise. The buy-

ing of supplies is lessening and future demand is comparatively quiet.

Dullness to Continue

The passing of the old year finds the old material market in the same stagnant condition that has featured its existence for several weeks back. That the early future holds little of interest is the opinion of many dealers, but some are looking forward to more active business as the winter is advanced. Prices which have obtained for the last month are still quoted but should be considered as nominal only, nearly every sale being made on its individual merits. If anything, the prices quoted are above those paid by the dealer.

WINDING UP THE YEAR'S AFFAIRS

Nearly All the Firms Have Had a Good Year, Though Hard to Get Required Material

TORONTO. — Many of the machine tool houses are busy just now getting their affairs of the year in readiness for the preparation of annual statements. They are finding out now whether they have bought wisely and turned over the stock quickly enough. One Toronto manager, speaking of this matter said this morning: "It is much harder running a business now than it was a few months back, when everything was on a rising basis. Then we could go ahead and buy, knowing that before we would get rid of the lot the price would have gone up again. The makers in many cases were so busy that it was impossible to buy too heavily, as their capacity prevented that. Just now it is quite different, and we are working in a declining market, and supplies must be bought with that in mind. When we send out a requisition now we inquire about delivery on the lines mentioned before placing the order. If we find that the deliveries are all right and can be made from stock, as a general thing we cut the requisition in two, knowing that we can order from stock at any time and get supplied. If we find deliveries are delayed we allow the requisition to stand. I don't suppose it means that we are doing any more or any less business, but it protects us in a market that is on the way down, and we feel safer for the present going along that way."

Have Had a Good Year

Machine tool men are not complaining about the business they have done during the year, neither are they willing to admit that it has been as profitable as the insistent nature of the demand might lead one to believe. Deliveries were very backward in the schedules of a good many makers, and in this way the dealers were not able to get through as much business as otherwise would have been the case.

Neither is there any complaint made right now, although sales have been few during the week. There is a certain feeling that business is going to be better, and that once the corner is turned the recovery will be quite brisk and satisfactory. Dealers are doing very little buying for stock, being content to place orders when they have a sale, knowing that in nearly every case they can secure tools out of stock now, something that has been quite out of the question for a good many months—yes, years in many lines.

The Steel Market

The year just closed has been a good one and yet a disappointment for many firms in the steel business. Good because there has been plenty of business—disappointing because of their inability to secure material in sufficient quantities to take care of the business that was offering. It is quite correct that many yards have done a larger volume of business and made less money than many people imagine. Merchants, rather than let their stocks run out, were forced to buy where they could, and paid premiums that had the effect of shoving up the price. In this way they could not recover the same margin as when they were selling at normal figures, and more money has been required to finance the same volume of business.

Hard to Secure Material

There have been several months in this year's business where firms in Canada which had to have steel in order to run their business have been put to no end of trouble to keep things moving in their direction and no small amount of enterprise has been displayed in a number of cases. For instance, the makers of agricultural machinery have kept men in the rolling mill districts, and at junction points and at any other spot where they felt it would be necessary to give attention to the movements of their shipments. This was especially so during the strike on the railroads. One firm which depended on a supply of cold rolled kept their own crews in the mills, where they were being looked after, and their own trucks, taking the material as soon as it left the mills and trucking it some twenty miles to the nearest point where railway connection could be secured. It cost a lot of money to see that shipments were turned out and headed toward the Canadian border, but if the Canadian consumers did not take these precautions they were faced with the poor alternative of shutting down their plants until conditions should right themselves. All this activity cost money and plenty of it, and increased costs of manufacturing in Canada in a way that is not generally appreciated by those who did not have to face the conditions described above.

Little Buying Now

The close of 1920 finds buyers in general standing pat in the matter of placing business. Many of them are full of

POINTS IN WEEK'S MARKETING NOTES

Steel and iron bars are quoted in Montreal warehouses at 4½ cents a pound, being a reduction of ½ cent from the last price.

—

Machine tool men as a general thing have had a good year's business, the one drawback being their inability to secure delivery when the selling was good.

—

The steel warehouses are rather quiet this week and buying has narrowed down to immediate wants. The warehouses themselves are not taking in very much material.

—

The end of the year finds the scrap metal market in much the same condition that has prevailed for the last three months. Many of the yards are doing practically no business at all and more money is being lost than made.

—

The majority of the independent steel mills are idle for the holiday week and there is some speculation as to when they will open again.

—

A number of steel mills in United States outside of the Corporation have announced reductions in wages, running as high as 20 per cent. A wage reduction by the Corporation is not looked for at the present time.

—

There is less talk heard just now of any reduction being made in the price of steel and it seems likely that the schedule of the Corporation will be approved by the independents and there the matter will rest.

—

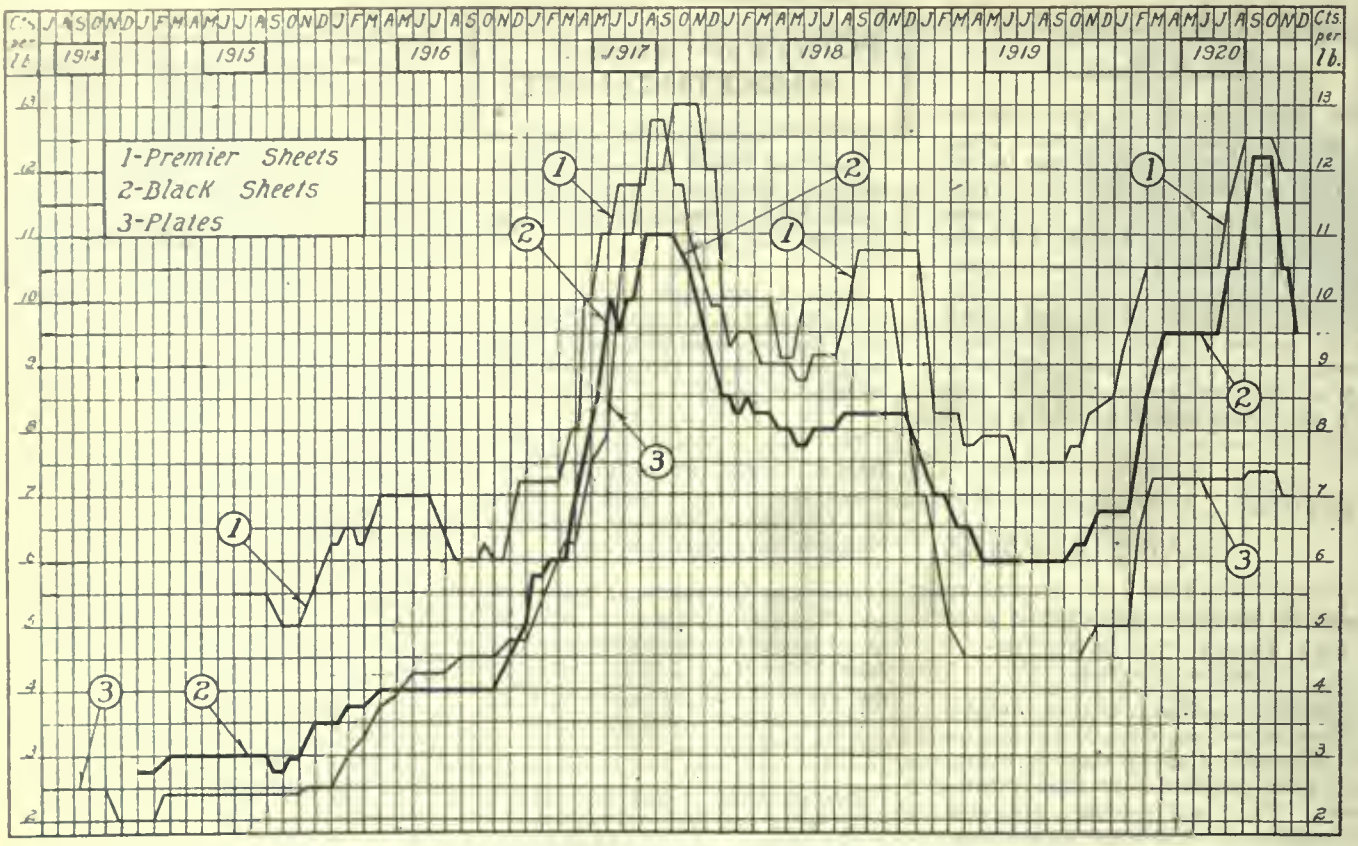
The selling of small tools is done only in small lots and users are not taking on anything in the way of surplus stock.

—

Representatives of Canadian firms returning from England report that German goods, especially all lines of cutlery, are being sold in London stores and are giving more competition to British goods than was thought possible a few months ago.

—

Very little pig iron is being sold in the United States or Canada at the present, and the market appears very weak. A requisition for a good sized tonnage would probably set a new low level.



PRICE CHANGES IN WAREHOUSE QUOTATIONS FROM 1914 TO 1920.

ideas as to why others should rush into the market and buy heavily, but they cannot see for a minute why they should follow the same course themselves. Warehouses probably have sufficient to meet the demands of the present, which are fairly light.

Information from some of the large steel concerns warrants the belief that they are not looking forward to any extended period of depression. They claim that steel bought now is for actual and immediate consumption, and in this way none is being piled at the yards or at the plants of the consumers. Cancellations are not as serious as was anticipated, and many applications of users for cancellations have been converted into business again with delivery for the first quarter of 1921.

MORE INQUIRIES IN NEW YORK MARKET

But These Have Not Been Changed Into Real Businesses Yet—Next Year's Prospects

Special to CANADIAN MACHINERY.

NEW YORK, Dec. 27.—The year 1920 has been one of ups and downs in the machine-tool trade. The early part of the year was marked by very satisfactory buying, which began to taper off about the middle of the year, although some companies had good business up until September. The slump which hit the automobile industry was the beginnine of a downward trend in orders, which by the end of the year had reached a point of stagnation. Not in many years has the machine-tool industry of the United States known conditions so quiet as those through which it has passed in the last two months.

All eyes are naturally turned toward the new year, which is expected to bring forth some improvement. The tangible evidences of this prospective improvement are to be seen in a fairly good number of inquiries received in the past month or six weeks, most of which have not been acted upon. In postponing purchases those companies which have made inquiry have announced that buying will not be done until after January 1. Whether this means immediately after the turn of the year will be determined only by events. There is a hopeful feeling however, that there will be a gradual resumption of business beginning with January 1 or at the latest by February 1.

Christmas week was not productive of much new business or inquiries, nor is anything important expected to develop until after New Year's.

INDEPENDENTS MAY CUT WAGES BEFORE THEY START WORK AGAIN

Special to CANADIAN MACHINERY.

PITTSBURGH, December 30. — The great majority of the independent steel mills are practically idle this holiday week. Some had previously closed, but the bulk of the closing was done Christmas Eve. At some of the plants there were intimations that there might be resumption Monday, January 3, but it is very doubtful whether there will be much resumption at that time. A mill would not resume unless it had accumulated a fair volume of specifications during the period of idleness, as all the mills that closed had first completed all business on books. Then there is the matter of wages, as most of the independents are disposed to reduce the rate. In the past two weeks, prior to this week, operations by the independents, considering that some were closed entirely, probably averaged between 30 and 35 per cent. This week, with few plants running at all, and then only at low rates, the average of the whole is probably under 10 per cent.

The United States Steel Corporation has closed a plant or department here and there for the holiday week, not on account of lack of orders, but for the purpose of making necessary repairs or to allow one department to catch up with another. The major portions of the Pennsylvania tube works in Pittsburgh and National tube works at McKeesport are down for the week, one to make repairs and the other to allow finishing departments to work up stock, accumulated by the primary operations getting

The Deciding Factor

AT this season of the year, we wish to extend to our many patrons, thanks for co-operation during the past and the assurance of our best efforts in the future, to provide that satisfactory service on which all true success is built.

As Canadians, we have confidence in Canada and Canadian institutions. We believe the future is secure, not so much on account of our unrivalled natural resources and the potential value of our manufacturing industries, but because, in the development of the Canadian Nation, we have learnt to know ourselves. Under exceptionally critical circumstances, the inborn genius of the Canadian people has invariably risen to the occasion. It is this sure knowledge of our capabilities, which will be the deciding factor now, and in the days that are ahead of us.

Our Service Department is imbued with the spirit of optimism, which is so necessary to the accomplishment of successful enterprise. Bring your problems to us. The experience of more than half a century, in working out the solution of manufacturing difficulties, is yours for the asking.

ahead. Apart from temporary closings this week the Steel Corporation is operating at over 90 per cent., or at a better rate than its average during the first ten months of the year.

Wages

It seems to be an established fact that the Steel Corporation will not reduce wages at this time, or until there has been a material change in conditions, particularly the corporation's own position, from that now existing. The independents are strongly disposed to reduce wages, but the Steel Corporation leadership, quite conspicuous in the various wage advances of the past five years, is absent. Furthermore, the independents do not confer together on any subject, either prices or wages, that having been considered undesirable for years on account of the state of public sentiment. Thus there is no opportunity for the rise of a general policy and each independent has to "go it alone." A few of the mills have taken action already. The Midvale Steel & Ordnance Company has made reductions at its Johnstown and Coatesville works, in Pennsylvania, the Wheeling Steel Corporation, operating chiefly in the Wheeling, W. Va., district, and a plant at Buffalo have lately announced reductions, to be effective this week, averaging about 20 per cent., with elimination of overtime payments in addition. Possibly some additional announcements will be made this week. A common guess is that many independents will announce wage reductions before they resume operations, the time of resumption being uncertain. If this proves to be the case it is probable that by about the middle of January the majority of independents will have announced wage reductions.

The problem is a difficult one for the independents. There is the lack of Steel Corporation leadership, already mentioned, on which the independents have so often depended, in various matters, in the past. Then there is the difficulty that while in some respects January 1 seems a good date for a wage reduction, the cost of living has been decreasing more or less steadily and further declines are expected in the future, while furthermore men would be more ready to accept a reduction after they had had a period of idleness. In particular, the cost of living depends largely on retail store prices and it is the feeling of all steel manufacturers that the retailers have not reduced prices as they should. A wage reduction, particularly in a town where the employees of the plant involved furnish the chief custom for the retail stores, would stimulate the retailers to reduce their prices. Thus, from one viewpoint the employer should wait for the cost of living to come down, while from another viewpoint he should make the reduction at once in order to help the cost of living to decline. One idea has been this, to make a small reduction now and another later, but a difficulty about this, in the minds of some of the steel makers, is that upon the appearance of the second reduction the buyers of steel would probably feel that they were entitled to lower prices. According to what practically all the independent mills say now, the Steel Corporation or Industrial Board prices are going to be maintained indefinitely, and thus anything that would encourage talk of lower steel prices would be very objectionable. There are some observers, however, who insist that no matter how steel producers talk there will eventually be lower prices for steel before there is any general buying movement and before prices firm up and start advancing again. No definite predictions are made as to when such declines will come, whether in two months or many months.

Steel Prices Held

The finished steel market, as far as quoted prices go, is holding better than many people expected. There are some reports of price cutting, but not many, and in general the markets are being held. This may possibly be due to there having been so little enquiry that adequate temptation to cut prices has been lacking, and if so the turn of the year may see a more open market, for such a period of dullness as has prevailed in the past few weeks cannot be prolonged. There is another point, however. A mill cannot operate economically unless it has a fair tonnage. To cut prices and get a light operation would hardly pay, complete idleness involving less loss. As the steel mills are all in very comfortable position financially they have no incentive to operate except to make real profits.

The independent market on standard steel pipe continues at $7 to $10 above the Steel Corporation or Industrial Board list. There is a rumor that some or all of the independents will issue a new card January 1, conforming to the standard card. While the pipe mills have been running very well on orders they have had some cancellations and postponements and cannot run on orders

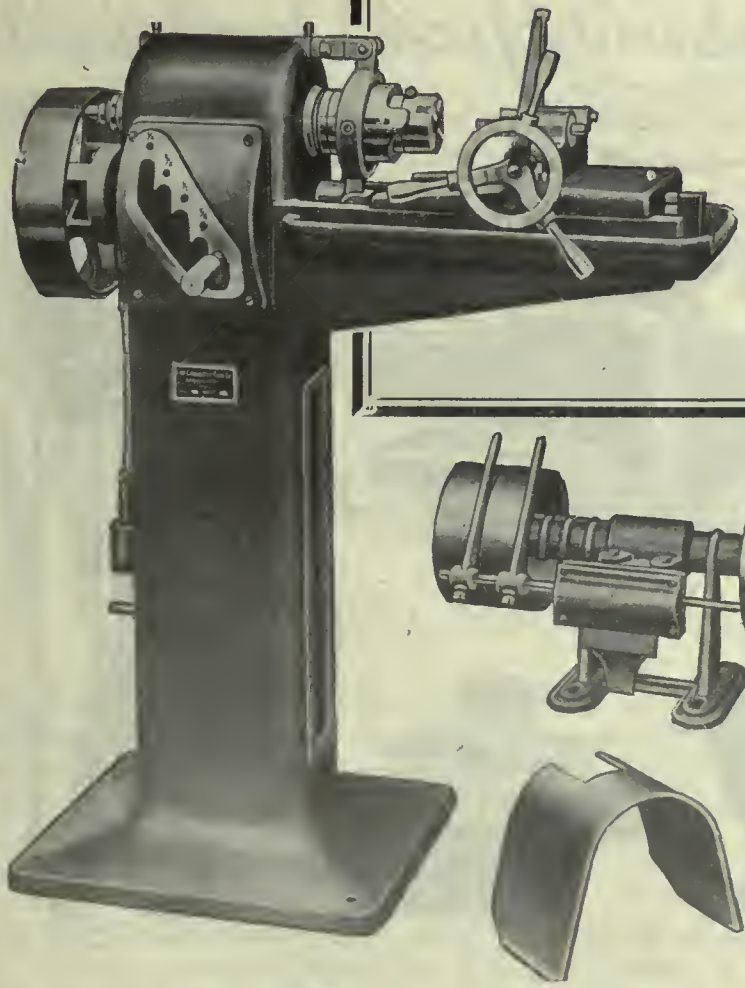
THIS WAY, PLEASE

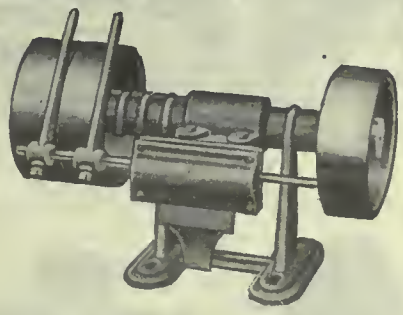
Where quantity and exactness have to be considered, the Geometric Threading Machine is just the way that suits. These machines have been tested and proved over and over again on speed, accuracy and endurance.

Geometric Threading Machines are employed on a large class of small threaded parts that cannot be produced economically on the ordinary screw machine.

Made in three sizes—to cut ⅛ to ½ inch, ¼ to ¾ inch, and ¾ to 1½ inch diameter threads. The carriage is mounted on slides and on the largest size machine is moved back and forth by rack and pinion, and in the smaller sizes by hand.

Spindle speed changes readily made, adapting the machine to the diameter and material of the work. An adjustable stop assures accurate length of thread, and automatically opens the die head, permitting of drawing the work straight back.





A line from you brings full details regarding this machine. Tell us your threading requirements—let us recommend the proper Geometric Collapsing Tap or Self-opening Die.

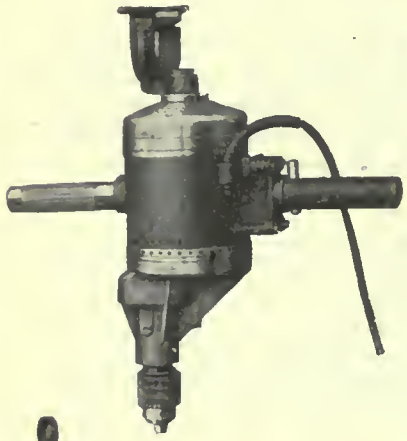
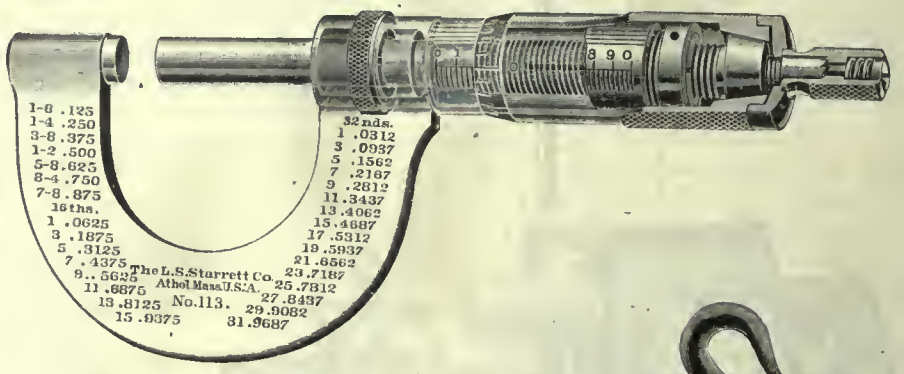
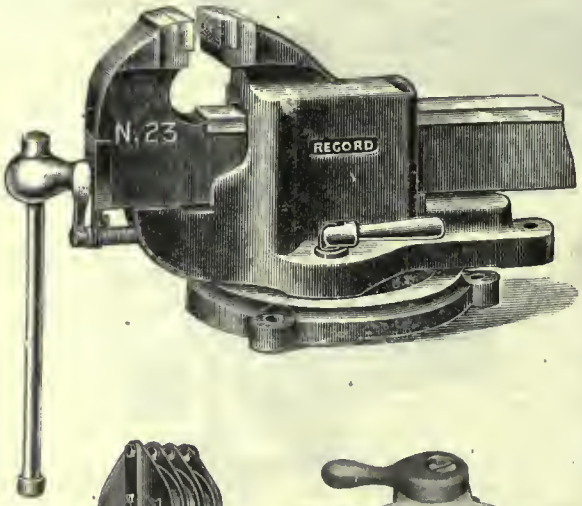
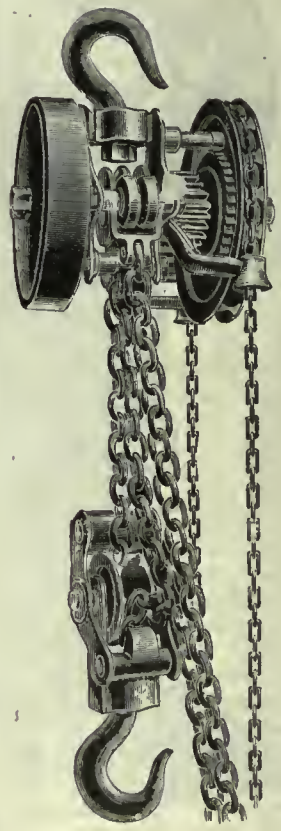
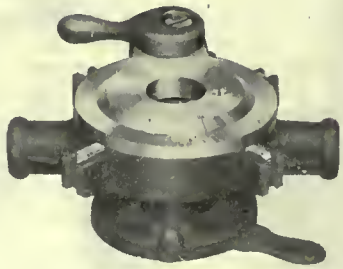
PROMPT SERVICE ALWAYS











When You Require Tools Think of Aikenhead's!

Aikenhead's

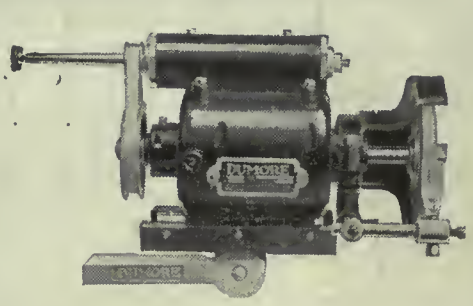
Canada's Leading Tool Supply House

The reputation of a manufacturer's product is his greatest asset. The firm which represents him to the purchaser must have a reputation equal to his own.

Aikenhead's is the Canadian headquarters of many makers of the world's finest tools.

DUMORE

High Speed Electric Grinders



Dumore Portable Electric Grinders are extremely light, powerful and accurate. These features, and the high speed at which they may operate, have made them standard equipment in thousands of machine shops and tool rooms. Dumore Grinders are made in styles for all small grinding. Their speeds run as high as 50,000 R.P.M.

30,000 R. P. M.

Once you use them, you'll find them indispensable. See Aikenhead's for a free trial.

WAHLSTROM'S TAPPING ATTACHMENT

Eliminates Tap Breakage

The Wahlstrom prevents the tap from jamming in the hole by keeping the lands free from chips—consequently there is no tap breakage. The chips are freed by an oscillating motion which duplicates the simple to-and-fro motion of hand tapping. For tapping in soft materials the oscillating motion can be changed to a continuous revolution.

The Wahlstrom fits any drill press. It is made in two sizes. No. 1 takes taps of all sizes from 5-40 to ½ inch, No. 2 takes taps from ¼ inch to ¾ inch. It has nothing to get out of order. **Write Aikenhead's for fuller particulars!**

MAY CUT WAGES

Continued from page 212

for more than a very short time longer. However, it is the regular thing for pipe mills to carry stocks and ship from stock rather than current production. Hence the mills may hold their prices and make stock, as they have practically no stocks at present. The old practice may be resorted to of putting out a 30 or 60 days' guarantee, whereby if a new list should be issued, say February 1 or March 1, all shipments to jobbers' stocks for 30 or 60 days previously would receive an adjustment equal to the reduction.

A little foundry iron has changed hands at $35, valley, enough to show that the quotable market has not changed. Bessemer and basic have remained stagnant, with prices nominally unchanged at $35 and $33 respectively, valley. The idea has become prevalent that some of the furnaces will formally announce price reductions January 1 or within a few days afterwards, possibly to about $30 for basic iron. The date has some significance, since several of the furnace interests will then get on to lower priced coke contracts and thus will have lower costs.

Some additional contract furnace coke business for the first half of the new year is reported as closed on the general basis of 5 to 1 against basic pig iron at valley furnaces. On $30 pig iron this would mean $6 for the coke. Altogether about 75,000 tons a month has been put under contract on substantially this basis.

NEW INDUSTRY AT PORT ARTHUR

In a large advertisement appearing in a recent edition of a Port Arthur paper, there is an announcement of the Port Arthur Shipbuilding Co., in which is recounted the falling off in the shipbuilding industry. The announcement goes on to state:

"Anticipating this condition of affairs, we have commenced the construction of pulp and paper machinery, and compressed air mine shovels, which work will, we hope, take up the slack caused by the falling off in shipbuilding. We have, however, in this new line, to go into competition with established manufacturers of long experience in this class of work. To succeed will mean not only continued prosperity for us, but the continuation of our quota of the prosperity of our city and the steady employment of the men who comprise our organization. Such success is what we are striving to attain for 1921, and we ask each and every one of our employees to unite with us in this purpose for the good of all concerned, and the welfare of the city in which we live. Of the citizens of Port Arthur, we ask a continuation of the co-operation and goodwill that they have given us in the past."

IRON, STEEL AND METALS SHOULD BE IN DEMAND DURING YEAR 1921

By W. S. LESLIE, of the A. C. Leslie & Co., Montreal

THE past year has been one of great changes in the metal market, some of these having proved disastrous to many manufacturers and dealers.

In iron and steel the scarcity prevailing at the end of last year was continued for the greater part of 1920, this condition being intensified by transportation difficulties, especially by the long drawn out strike of switchmen in the United States and also by the shortage of fuel. This shortage resulted in an abnormal advance in price of coal and coke, which forced makers who did not control their own supply to further advance their prices for iron and steel products, and, while the United States Steel Corporation steadily maintained their prices, they were unable to keep up with their deliveries and even buyers who had contracts running at moderate prices were obliged to go into the market and pay heavy premiums for prompt or fairly prompt delivery. For the past few months, however, transportation conditions have been about normal and the fuel situation having been considerably relieved, makers have greatly improved their deliveries, and on this account the premiums commonly paid have been greatly reduced. In fact, the market is getting down to a point somewhere near the level established by the Steel Corporation.

This downward movement has been quickened and carried farther than would naturally have been the case by extensive cancellations and postponing of deliveries on the part of buyers, chiefly in the automobile and allied industries, and these conditions have naturally made buyers hold back and probably they are carrying this policy to an extreme.

British manufacturers were able during the year to regain some of their lost trade in Canada, being assisted by the scarcity of American material and the low rate of Sterling exchange. Great Britain also, and probably their products, will be more in evidence in the coming year. Already a considerable quantity of galvanized and a smaller quantity of black sheets and tinplates have been imported and prices now being quoted are interesting for delivery at points where freight rate favors British imports.

The high price of fuel, however, in Great Britain and a shortage of pig iron have prevented any reduction in prices of the less manufactured forms of iron and steel that would make shipments to Canada possible.

The course of the non-ferrous metals has been most erratic. For the first five or six months of the year, tin, copper, lead, spelter and other metals were all very strong, though prices of some, more especially copper and spelter, were not abnormal compared with pre-war levels. A very serious slump, however, has since taken place in all these metals and values have apparently been carried lower than cost of production justifies, with the possible exception of lead, the supplies of which are comparatively small. Financial reasons, coupled with the fact that these metals are speculated in very heavily, account largely for the continued slump, and while there should undoubtedly be a good reaction in price of these metals, it is a question how soon this will take place. Certainly there must be more confidence than now exists before the market will be stabilized.

From what I have said the present would appear to be a time for buyers to continue a cautious policy in purchasing without allowing themselves to run out of supplies, but there is no reason why the demand for iron, steel and all other metals should not be good during the coming year, as there is a large amount of buying to be done when buyers have sufficient confidence, and are able to finance their requirements.

ATKINS
METAL CUTTING SAWS

Solve your Metal Cutting problems, easily, quickly and economically, by adopting the products made by

ATKINS

We make Kwik-Kut Power Hack Saw Machines which use practically the full cutting edge of the Hack Saw Blade at each stroke; Metal Cutting Band Saw Machines for general shop work, cutting all classes of metal up to 12 x 14 inches.

Your requirements for Metal Cutting Circular Saws can be supplied promptly and we solicit a trial of our "AAA" Non-Breakable and Power Hack Saw Blades and Frames.

CAM
FOR DIE HEAD

Attached to the toolpost of the engine lathe on which this cam has been machined, the Dumore Grinder accurately grinds the hole without necessitating another "set up." The high efficiency standards of the Geometric Tool Co. (New Haven Conn.) make comment unnecessary on this method of handling the job. It is sufficient that the work of the Dumore is so satisfactory, the finish so fine, that all cams this size or larger, made in this shop are ground in this manner.

The Average Shop Has Constant Use for Dumore Grinders

Dumore Grinders are made in types and sizes that can be attached to all classes of machines and used to successfully perform a wide variety of grinding operations.

Equally valuable for the important "odd jobs" that must be done in every shop and on some manufacturing work, they find a ready place in every part of every metal working plant—whether toolroom, factory or repair shop.

Ask us about DUMORE Grinders—full details on request.

Machine Tool Designers Have Had a Busy Year

Brief Statements Touching on New Developments in Machine Tools and Kindred Lines—Grinders, Presses, Shapers, Planers, Drills, Lathes, and Miscellaneous Tools are Included

DURING the past year many new developments in the machine tool industry have taken place. These developments have been recorded from week to week in Canadian Machinery and the list to follow are only some that we have covered during the year. Of course, greater detail was given than that which follows, but this list is more of a handy reference for our readers rather than a description of the tool itself. Should a reader be interested further, he has merely to drop a line to the firm, in this way securing all the data.

Grinding Machines

The Fitchburg Grinding Machine Company, Pittsburgh, Pa.—A line of plain cylindrical grinding machines. Spindle is of tool steel, and spindle boxes of bronze, these boxes being provided with means of compensation for wear. Automatic cross feed is operated at each reversal of table and is self-releasing when work has been ground to size. These machines are built in six sizes.

The Badger Tool Co., Beloit, Wis.—A new line of grinding machines in which the spindle is fitted with both radial and thrust ball-bearings.

The Grand Rapids Machine Co., Grand Rapids, Mich.—A new line of tap grinding machines for grinding the taper and clearance on the ends of taps.

The Precision and Thread Grinding Mfg. Co., Philadelphia, Pa.—Several grinding attachments that are particularly adapted for thread grinding on lathes. Any style thread can be ground with these attachments. Grinding spindle is carried on ball-bearings, and is adjustable for radial wear and end thrust. Power transmission is accomplished by an endless belt which has a three-point contact with both the driving and driven pulleys. The belt then travels over a compensating two-pulley arrangement, which automatically keeps it at the proper tension to prevent slippage.

The H. F. Harris Engineering Co., Bridgeport, Conn.—An automatic hob grinding machine which embodies various interesting features.

The Lafayette Tool & Equipment Co., Philadelphia, Pa.—A universal grinder for precision tool room work. Both internal and external thread gauge grinding can be performed. The machine can also be used on the bench or as a grinding attachment for lathes, milling machines, shapers, planers, etc., etc.

The National Machine Tool Co., Racine, Wis.—A combination tool cutter and gauge grinding machine. Especially adapted for tool room or machine shop. Will grind cutters, arbors, reamers, mandrils, etc., between centres, or on large or small lathe. This machine can also be used for lapping small dies, bushings, also snap gauges.

The Badger Tool Co., Beloit, Wis.—A new double spindle type disc grinder. This machine is intended for finishing two opposite parallel faces of work at one time, such as drop-forged wrenches, piston rings, nuts, etc.

The Mummert-Dixon Company, Hanover, Pa.—A special design of portable grinding machine. This machine is self-contained and the wheel may be operated at any desired angle without interfering with the general alignment.

The Van Dorn Electric Tool Co., Cleveland, Ohio.—A small aerial grinder, which may be obtained for D.C. or A.C. current. Ball bearings are used throughout.

The Diamond Machine Co., Providence, R.I.—A heavy duty face grinding machine that is intended for grinding operations on heavy equipment that is usually accomplished on planing machines.

The Wordell Manufacturing Co., Cleveland, Ohio.—A new automatic metal cutting circular saw grinder. This machine will re-sharpen all screw-slotting, slitting and cold saws from 1½ inches to 18 inches diameter, and with teeth from 36 to the inch up to 2 inches from point to point. Saws are resharpened at a speed of 45 teeth per minute. The machine is fully automatic and once started requires no further attention.

The Bellevue Industrial Furnace Co., Detroit, Mich.—A line of automatic drill grinders. These grinders are said to sharpen a drill to a perfect angle. The machine is driven by an electric motor in the pedestal and is equipped with two-step pulleys so that two speeds are available.

A. B. Jardine Co., Hespeler, Ont.—A pedestal grinder for general grinding and polishing in machine shop, blacksmith shop, automobile shop, etc.

The Precision Trueing Machine & Tool Co., Cincinnati, Ohio.—A grinding wheel trueing machine. This machine can be applied to any style of grinder and is operated by either alternate or direct current.

The Beacon Engineering Co., Tipton, Eng.—A twist drill grinder for drills up to 1¾", also a sensitive pillar treadle drill for holes up to ½".

The Bryant Chucking Grinder Co., Springfield, Vt.—A machine for the grinding of holes, also exterior surfaces. The machine is made in two types, single spindle and double.

Various Types of Presses

The Enterprise Machinery Co., Chicago, Ill.—A bench forming press that is intended for the rapid assembling of small parts and for such operations as seaming and riveting on hollow work.

The Lasalle Machine Works, Chicago, Ill.—A line of bench presses designed for accurate production of small parts, such as used by jewelers, typewriter manufacturers and for other kindred work.

The Streine Tool & Mfg. Co., New Bremen, Ohio.—A new toggle forming press for roofing, and special shapes, with a capacity up to 12 ft. in length. This machine is also provided with tables for die work.

The Toledo Machine & Tool Co., Toledo, Ohio.—These people have brought out a considerable number of very large presses during the past year.

Williams & White Co., Moline, Ill.—A new straight side press which has a working length of 16 ft. between the housings and is capable of exerting a pressure of 300 tons distributed load.

The Package Machine Co., Springfield, Mass.—A precision bench lathe on which the headstock is fitted with ball thrust bearings.

Shapers and Planers

The Columbia Machine Tool Co., Hamilton, Ohio.—A varied line of heavy duty shapers ranging from 16" to 28" capacity.

The Simmons Machine Co., Albany, N.Y.—An open-side planer that will take work 42 in. wide, 48 in. high and up to 12 ft. in length.

The Turbine Air Tool Co., Cleveland, Ohio.—A line of air planers which are used for shaving telegraph poles and is used on general construction work.

The Oliver Machinery Co., Grand Rapids, Mich.—A new direct-coupled, motor-driven, ball-bearing hand planer and jointer.

Alfred Herbert Co., Ltd., Toronto, are handling a special planer that is known as the Hilo-plane and which is electrically controlled.

The Universal Machine & Tool Co., Canton, Ohio.—A new 24-inch open side planer which is said to combine the

Morrow Drills

Put to the File Test

EVERY Morrow High-Speed Drill is subjected to this rigid test—if it doesn't **"pass"** it is thrown out. There's no guesswork—if the drill isn't up to Morrow Standard you don't get it.

Order by the name.

If interested tear out this page and place with letters to be answered.

advantages of both shaper and planer. Variable stroke mechanism is used for driving the table, the speed of which is varied by means of shift gears.

Milling Machines

The Garvin Machine Tool Co.—A form miller of horizontal type. This machine is designed for cutting flat or cylindrical cams, and worm gears drive the work arbor. Power is transmitted through spur gearing, three changes of feed being given for the flat cam-cutting fixture. All gearing is housed, protecting it from damage or injury to the operator.

Marshalltown Manufacturing Co., Marshalltown, Iowa.—A plate milling machine for milling the edges of boiler plates. These machines are made in four sizes, having a range from 8 to 24 feet.

Tri State Milling Machine Co., Memphis, Tenn.—A milling machine attachment that has been adapted for use on shaping machines.

The Gabrielson Mfg. Corp., Syracuse, N.Y.—A new manufacturing type of milling machine. These machines are built in three sizes: 6, 9 and 12 inches between the spindle and table.

The Automatic Machine Co., Bridgeport, Conn.—A multiple spindle profile milling machine that is automatic in action. This machine is specially adapted for automobile work.

The Kempsmith Mfg. Co., Milwaukee, Wis.—A new vertical maximiller. This machine is of the usual type, but of very rigid design. Quick power traverse has been arranged, giving 100 inches per minute travel of the table in either direction, and 36 in. per min. on the vertical and transverse movement. The lubrication of the machine has been carefully gone into.

The Taylor & Fenn Co., Hartford, Conn.—A two-spindle spline milling machine that is automatic in operation and designed to simultaneously machine two spline grooves up to six inches in length on opposite sides of the same piece. Two cutters, operating simultaneously, reduce machining time on work where two spline grooves are cut. Work of any diameter up to 5 in. and of any length may be splined. The cutters can be made to advance either in unison or alternately and to knock off in like manner.

The Betts Machine Co., Rochester, N.Y.—A continuous milling machine that can be provided with whatever number of spindles desired.

The Toledo Milling Machine Co., Toledo, Ohio.—A new type of vertical milling machine. Unit construction has been adopted. Longitudinal table movement is 46 in., traverse 14 in. and vertical movement equal to the traverse. The spindle has a vertical movement of 6½ in.

The Ingersoll Milling Machine Co., Rockford, Ill.—A special type of reciprocating milling machine that may be designed to meet specific requirements. These machines are intended for working on duplicate parts.

The Ryerson-Conradson Co., Chicago, Ill.—A new helical drive high power miller. The proportions of this machine are adequate for heavy work, and as already stated, the drive is obtained through helical gears. Change gears are cut from solid, made of chrome nickel steel and are heat treated. Other gears are made of steel or bronze.

The Brown & Sharpe Mfg. Co., Providence, R.I.—A special automatic milling machine which is essentially a manufacturing machine and is used in plants where duplicate work is obtainable.

The Superior & Engineering Co., Detroit—A hand milling machine that is driven by a 1½ h.p. motor. Spindle has 12 changes of speed ranging from 100 to 600 r.p.m.

Various Types of Drills

The Joseph T. Ryerson & Sons, Chicago, Ill.—A new high power, plain, radial drilling machine.

The Arthur C. Mason, Inc., Hawthorne, N. J.—High speed, sensitive, ball-bearing drilling machine. Various features have been incorporated, some of these being elimination of frictional bearings, absence of belt trouble, and direct drive. Machine is equipped with ball-bearings throughout, and all moving parts are protected. Four spindle speeds are arranged for, these varying from three thousand to ten thousand r. p. m. This machine is also made in bench type.

The Arthur C. Mason, Inc., Hamilton, N.J.—A heavy type of sensitive drilling machine. The spindle of this machine is equipped with ball bearings throughout.

National Automatic Tool Co., Richmond, Ind. — An inverted drilling machine which is said to be advantageous for the drilling of deep holes in cast iron.

The Barnes Drill Co., Rockford, Ill.—A gang drill built for heavy duty work. Spindles are exceptionally large and double spindled. This machine will drive a 2-in. twist drill at .041 in. feed per revolution of spindle, or at the rate of 6½ in. per minute in cast iron, without the gears.

The Niles-Bement-Pond Co., N.Y.—A new type of radial drilling machine. This machine is built in two sizes, 5 ft. and 6 ft. arms.

The Sibley Machine Co., South Bend, Ind.—An addition of two sizes to their regular line of drill presses.

Danber Kratsch Co., Oshkosh, Wis.—Upright drill press with all gear feed. Drive for machine consists of semi-steel and rawhide gears. There are no sliding gears in the gear box. Speed may be changed by single movement of clutch lever. Spindle has ball thrust bearings at lower end, and four changes of feed for each spindle speed is provided.

Joseph T. Ryerson and Sons Co., Chicago, Ill.—A high power, radial drilling machine. These machines are made in three sizes, four, five, and six feet arms. Ball bearings are installed.

Hilldrill Co., Philadelphia.—Gang drilling machine. Drill spindles are chain driven, and flexibility of chain drive makes it adaptable for gang drilling on any type of work. The cycle of operations is automatic, and the spacing of spindle is universal. Special mechanism clamps the work in place with a pressure of about ten tons. The drill heads are built as independent, detachable units.

The Morris Machine Tool Co., Cincinnati, Ohio. — Three sizes of radial drills, 2½ ft. 3 ft. and 3½ ft., respectively. Various features have been embodied, and with the exception of large spindle gear, all other gears are made of steel. Gears are fully inclosed and run in light grease or heavy oil. Six feeds are secured. Friction clutches in speed box and tapping attachment are of expanding ring type. Motor drive can be arranged if desired.

Genesee Mfg. Co. Rochester, N.Y.—A special tool for use in drilling machines, for the counter-boring of holes, facing, forming, and similar operations.

Lathes

The Canada Machinery Corp., Galt, Ont.—This concern has brought out a 16-inch by 20-inch shaper and a 42-inch engine lathe. The lathe is equipped with clutch control from the saddle, and an all gear head is driven by motor through silent chain drive. There is an internal gear face drive to the face plate.

R. A. Kelley Co., Xenia, Ohio.—A redesigned shaper which is said to be a considerable improvement over their old design. A special feed box is fitted to the ends of cross rails and feed is automatically disengaged at the end of the travel. Helical teeth are used on all gears and pinions.

Joseph T. Ryerson & Sons, Chicago.—A line of high power selective head engine lathes.

Alfred Herbert, Ltd., Coventry, England.—A universal turret lathe. A heavy duty combination turret machine, and heavy slotter. A new type of hexagon turret lathe that is suitable for both bar and combination turret lathe work. A new hydraulic turret lathe originally in-

THE MASSEY-HARRIS CO. HAVE A WELL-APPOINTED EMERGENCY STATION WELL FITTED UP

Healthy, Contented Workers Mean Greater Production

ACCIDENTS occur almost daily in Industrial plants; workers are incapacitated, time and money are lost, the men's spirits are demoralized. Safeguard against these possibilities by equipping a thoroughly modern, practical and efficient First Aid Department—a place where minor ills as well as serious accidents can be cared for. In this way the men will know you have their interests at heart—they will be more loyal, do better work and increase production.

Let us advise you regarding suitable first aid equipment. Our stock is very complete and consists of

If interested tear out this page and place with letters to be answered.

tended for use by disabled men. Chuck turret and cross slide are operated by means of hydraulic cylinders.

The Cincinnati Lathe and Tool Co., Oakley, Cincinnati.—A new line of gear head lathes. Seven sizes are made. These lathes are fitted with hexagon turret on bed, and power feed silent chain drive. As the speed variations are obtainable in the head, constant speed motors only are required. Twelve speed changes in geometric progression are secured on these lathes. This is accomplished through sliding gears and by shifting three levers.

The Seneca Falls Manufacturing Co., Inc., Seneca Falls, N.Y.—Two sizes of gap lathes, eleven inches by eighteen inches, and thirteen by twenty-one inches swing. These machines have wide range for screw cutting of all standard threads, from 3 to 72, including 11½ and 27 pipe threads.

O. R. Adams, Mfg. Co., Rochester, N.Y.—A lathe known as a short cut lathe. The head stock of this machine is designed to give 6 changes of speed with a range from 43 to 375 r.p.m. Speed changes can be made while lathe is in operation.

Miscellaneous Tools

Charles Engelhard, New York.—An automatic temperature regulator that opens or closes control valve at desired temperature.

Canadian Firefoam Co., Hamilton, Canada.—A fire extinguisher known as Foamite Firefoam. Various capacity engines, also small hand tanks are supplied, equipped with this particular extinguishing fluid.

The Ricker Instrument Co., Philadelphia, Pa.—A line of precision levels for machine shop use.

The Independent Pneumatic Tool Co., Chicago.—Pneumatic motor hoists up to two tons capacity, the speed lift is 32, 16 and 8 ft. respectively for the half, one, and two-ton sizes.

The Link-Belt Co., Chicago, Ill. — A new friction clutch which has a one-point adjustment. All moving parts are enclosed and parts are balanced. Parts are easily accessible, if repairs are necessary.

Canadian Reclaimers, Ltd.—A pulpwood reclaimer that is said to eliminate considerable labor when stacking or unstacking pulpwood.

The Pittsburg Instrument and Machine Co., Pittsburgh, Pa.—A sheet metal tester that is used to determine the drawing, stamping, compressive, and folding qualities of sheets of iron, steel, brass, copper, etc., etc.

Link-Belt Co., Chicago.—A hydraulic system for raising or lowering heavy doors such as are used on open hearth and heating furnace work.

The Roberts Mfg. Co., New Haven, Conn.—An improved friction clutch that is adapted to drilling, tapping, and stud setting.

The Kent Machine Co., Kent, Ohio.—A two-spindle pointing machine that is intended for the pointing of bolts, or rods up to three-quarter inch in diameter.

Black & Decker Mfg. Co., Baltimore, Md.—An electric air compressor that is made in two types, namely high and low pressure. The largest of these machines will work up to a pressure of 200 lbs. per square inch.

The Wayne Oil Tank & Pump Co., Fort Wayne, Ind. —An oil filtering cabinet which is intended to be placed under the machine from which the oil is flowing.

The Lapoint Machine Tool Co., Hudson, Mass. — A new type of broaching machine, known as the No. 3 Duplex. The power screws may be operated jointly, or as separate units as desired, and to any required length of broach.

D. MacKenzie Machinery Co., Guelph, Ont.—New saw table. This machine is adapted to electric or gasoline drive, and is designed not only for factories but for manual training schools.

The Scully-Jones, Chicago.—A new drill chuck that is designed to hold a straight shank drill in a taper hole of the drilling machine.

Frank G. Payson Co., Chicago, Ill.—A special line of air operated chucks, for use on double spindle turret lathes.

The Yoder Co., Cleveland, Ohio.—A specially designed slitting shear that is said to remove any irregularities in the strip after it has been cut. On metal up to one-eighth inch in thickness strips as narrow as 2 three-quarters in. may be cut.

The Manhattan Machine and Tool Works, Grand Rapids, Mich.—A four-post screw press that is designed to suit all classes of arbor press work.

The Hoosier Drilling Machine Co., Goshen, Ind. — A new line of machine vises in which the jaws are of hardened steel, but may be modified to meet specific needs.

The Becker Milling Machine Co., Hyde Park, Boston, Mass.—A new machine known as Model D.1 die-sinker. Dies up to ten tons in weight can be accommodated. Centralized control is a feature of this machine. The spindle is back-geared and driven by a five-inch double belt. Thirty-two feeds are obtainable. Fourteen spindle speeds are provided. A seven and a half H. P. variable speed motor is used.

The Atlas Press Co., Kalamazoo, Mich.—Two new arbor presses, one 6-ton capacity, the other 15-ton. These presses are adapted for a variety of work, such as forcing arbors, straightening and broaching operations, etc.

The Cincinnati Gear Cutting Machine Co., Cincinnati, Ohio.—A new type of gear hobbing machine that has a maximum capacity of 17¼ inches diameter and 12-in face.

The Newton Machine Tool Works, Inc., Philadelphia, Pa.—A portable slotting machine that has a maximum stroke of 70 inches.

The Hercules Machine and Tool Co., Astoria, N.Y.—A gear hobbing machine which provides for exhaust adjustment in the centering of the hob. Automatic stops are provided for disengaging the feeds when machining the various classes of gears.

W. J. Pine Machine Co., Kenosha, Wis.—Straightening machine which combines a testing table and machine. Stock to be straightened is placed on upper testing table, then put in position under pressure screw. Operations performed on this machine are: offsetting connecting-rods and bars, bending irregular shapes in forms or dies, etc.

Volta Mfg. Co., Welland.—A furnace of the Heroult type. Furnace transformers have capacity of 1,500 K.V.A., and connection is made to the furnace catenaries by means of the usual copper busses. A tilting arrangement is provided. Furnace is balanced and a small-sized motor gives desired tilt.

The Stock Bridge Machine Co., Worcester, Mass. — A shaper attachment which will shape any irregular curve. Forming dies and various shaped blocks are possible with this attachment. A templet is carried in cross slide holder and is shaped to required outline of surface to be duplicated.

The Foster Machine Co., Elkhart, Ind. — A complete line of hand screw machines embracing five sizes. Several new features are noticed, but on the whole the machines do not represent any radical departure from established practice. Three different styles of cut-off units are supplied, being interchangeable. Power feed to turret is a separate unit, and machine can be built for power or hand feed.

W. S. Rockwell Co., New York.—New type of side-opening heat treating furnace. Furnace is 36 ft. wide, and doors can be raised or lowered independently, operated by compressed air and counter weight. Oil or gas can be used as fuel. Provision is made for convenient control of burners from above the floor level at rear of furnace. Doors are controlled by air hoist mechanism.

Burton Engineering & Machinery Co., Cincinnati. — A line of gasoline and kerosene locomotives adaptable for any gauge track. These are built from three and a half to twelve tons, and power is transmitted through a spur friction, and power shaft.

STEEL CASTINGS

We shall be glad to supply, in addition to our General Catalogue, literature on

Steel Castings — Lithographed Ware
Galvanizing — Enamelled Signs
Wire Goods
Stoves

Made by the Acid Electric process up to fifteen tons. Castings made by this process are free from blow holes, easy to machine, and superior in every way to ordinary Steel Castings.

Castings supplied for shipbuilding, cars, locomotives, all classes of machinery, etc.

TRY US FOR GENERAL REPAIRS

ALEXANDER FLECK, LIMITED

(Vulcan Iron Works) OTTAWA, ONT.

REFUSE CHANGE ASKED BY N. Y. C.

Step Preferred Instead of Pilot, But Ottawa Does Not See It That Way

OTTAWA.—Application of the New York Central Railway for a modification in the regulations regarding railway safety appliance standards which would permit the company to use step construction instead of pilot construction on its freight engines operating into Canada has been refused by the Board of Railway Commissioners. Dr. S. J. McLean, in refusing the application, states that "the board is asked to allow a departure from its regulations and to allow the substitution therefor of a practice depending entirely on tolerance."

Having in view Canadian conditions and the careful consideration given before the regulations were adopted, he advises refusal of the application.

The Railway Company represented that the step had every advantage that a pilot had, and that its use was allowed under the rules of the Interstate Commerce Commission. The step equipment was not, it was stated, objected to by any of the Public Utilities Commissions of the States through which the New York Central operated, and there would be difficulties in operation if a pilot was required for the portion of the journey in Canada.

PRODUCTION IS UNDER WAR MARK

Figures Given Out Concerning Amount of Iron and Steel Made in Canada

Production of steel and pig iron in Canada in 1920 has shown an increase over 1919, but the figures are considerably below the previous three years, when war contracts so greatly speeded up the output. According to a statement by the Department of Mines at Ottawa, the monthly production of steel in 1920 to the end of September averaged 105,931 tons, compared with the monthly average in the previous four years, as follows: 1919, 86,157; 1918, 156,954; 1917, 145,494; 1916, 106,268.

The monthly production of pig iron this year averaged 89,610 tons for the first nine months, compared with an average of the following in previous years: 1919, 76,482; 1918, 99,629; 1917, 97,540; 1916, 97,438.

The blast furnace plants active during the first nine months were those at Sydney and North Sydney, N.S., Hamilton, Port Colborne and Sault Ste. Marie, Ontario. The blast furnace plants at Midland, Parry Sound, Deseronto and Port Arthur, Ontario, were idle throughout the period. At the end of September ten stacks wer active and eight idle.

Pig iron was made from scrap iron and steel at four electric furnace plants, located at Hull, Montreal and Shawinigan Falls, Quebec, and Orillia, Ontario.

PIG IRON TRADE

That some pig iron users are busy is shown by purchases by rather important companies. Further concessions in price are noted. On the Pittsburg market No. 2 foundry may be obtained at $35 valley furnace. The leading independent steel company in this district has only about one-third of its furnaces making iron at present.

On the Chicago market the absence of transactions of any size makes it difficult to name ruling prices. Southern furnace prices are substantially the same as a week ago.

On the Cleveland market the inquiry is larger than in many weeks, but the volume of sales shows little change. Prices on foundry iron have settled down to $35 base for No. 2. Some producers believe there will be little resale iron on the market after January 1st.

At Boston less resale iron is offered than last week, presumably because of the lack of demand. The feeling among foundry owners is more hopeful, although business is quiet.

The pig iron market at Birmingham is at a standstill as there is practically no business being done. With so many furnaces out, a real buying movement would find very little to go on.

Inquiries are showing improvement, but sales are still light on the Buffalo market. Five hundred tons of resale foundry were sold at $34 to $35 base price per ton. The total inquiries for the week aggregate 3,000 tons, but little of this developed into the actual order stage.

The market is very dull in the Cincinnati district but several inquiries for first half of the year have appeared from outside this territory. Furnace sales continued light, there being no disposition to compete with resale prices on the inquiries appearing.

Iron does not seem to be wanted at any price is reported on the St. Louis market. Furnaces are making no prices, and submission of offers is one of the things more notable by absence than presence in the market.

On the New York market it is extremely difficult to determine prices with any accuracy as reports concerning resales indicate a wide variation in quotations. Several eastern Pennsylvania furnaces are expected to blow out or be banked within the next few days. Eastern Penn. No. 2 foundry 1.75 to 2.25 silicon delivered in New York district is quoted at $36.52 to $37.52.

The Philadelphia market shows further declines in the price of pig iron.

Engineering

Schools are being planned by the Boards of Ste. Apelline, and St. Sylvestre, Que.

The United Farmers of Manitoba, in the district of St. Andrew's, are planning the erection of a hall there.

Victoria Hospital, London, Ont., is to have a new nurses' home. The estimated cost is $100,000. Erection will begin in the spring.

The Pigeon River Lumber Co., Port Arthur, Ont., are rebuilding their planing mill and machinery, destroyed by fire some months ago.

The town of Lauzon, Que., is considering the installation of a new water works system. The estimated cost is about $300,000.

W. Harris and Co. have plans prepared for the erection of a private garage and office building on Keating St., Toronto, at an estimated cost of $25,000.

The Hydro - Electric Commission, Brantford, Ont., is planning to duplicate its system at a cost of $750,000. The new work is projected for the coming year.

Ottawa, Ont., needs a new fire station, and a by-law will be submitted to the property owners at the coming elections to raise the sum of $200,000 for the purpose.

It has recently been announced that the Trans-Canada Theatres, Ltd., are contemplating the erection of theatres at Guelph, Ont., Regina, Sask., and Vancouver, B. C.

The Live Wire Co., Ltd., a new concern in Guelph, Ont., are producing from 30 to 35 thousand feet per day of rubber-covered insulated wire.

The ratepayers, Dutton, Ont., will be called on early in the year to sanction the expenditure of $18,000 for improvements to the community hall on Main street.

Operations are commencing at the new factory of the Canadian Detroit Twist Drill Co., at Walkerville. Their productions will comprise drills, reamers and milling cutters.

Good progress has been made on the 18-storey addition to the King Edward Hotel, Toronto. The steel work of the first 12 storeys is already up and the floors are being put in as the steel work goes up.

A new town is springing up around the paper mills of the Spruce Falls Pulp and Paper Company at Kapuskasing, Ont. There are about 1,250 men at present employed by the mills. Work on the mills is going ahead rapidly and it is expected the first pulpwood unit will be in operation by May next. The sum of $500,000 will be spent on the establishing of this townsite.

The Semet-Solvay Co., the largest concern of its kind in the world, is considering the erection of a by-product coke oven plant in Hamilton, costing $4,000,000. It is said this would produce all the artificial gas necessary to meet Hamilton's needs for several years.

Announcement has been made that plans have so far progressed that preliminary construction work on the international bridge to be built connecting Detroit and Windsor will be started early in the coming summer.

BUYING A PIG IN A POKE

The buying of advertising space used to be buying "a pig in a poke." The quantity and quality of circulation was shrouded in mystery and often the bag was tied against investigation.

That day has passed. The advertiser no longer depends upon "mere claims." The Audit Bureau of Circulations has untied the strings to the sack and the circulation of the better class of publications is thrown open for the most searching scrutiny.

In buying advertising space in CANADIAN MACHINERY you are not buying "a pig in a poke." Our A. B. C. statements will stand the analysis of the most exacting investigator.

The House of PETRIE and its Founder

50 Years of Progress

H.W. PETRIE, Sr.

50 Years of Service

THE history of the Metalworking and Woodworking industries of Canada is closely linked with the Machinery and Supply House of H. W. Petrie, Toronto and Hamilton. When H. W. Petrie entered his chosen field fifty years ago industrial Canada was in its infancy; but it grew and grew, and the house of Petrie grew up with it and became a by-word in every quarter of Canada where Machinery is mentioned During its growth the house of Petrie endured and thrived through periodical trade depressions, political upheavals, wars and rumors of wars, for the good reason that a Petrie customer invariably comes back; he learns to expect quality, service and a square deal—and he is never disappointed!

It is interesting to note that the house of Petrie was founded at Brantford, Ont., where it had remarkable success. In 1890 the business was transferred to Toronto, where conditions were more in keeping with the rapid growth of the concern.

Commenting upon this the Toronto Globe in its issue of December 27, 1890, referred to Mr. H. W. Petrie as one of the best known dealers of Machinery in the Dominion, who for many years conducted a business in Brantford, and owing to able management and thorough knowledge of the making and handling of machinery found his business had outgrown the confines of Brantford; as a consequence the proprietor found it expedient to remove his plant and erect at a great cost the present commodious depot at Toronto, situated immediately adjoining the tracks of the Canadian Pacific and Grand Trunk Railways.

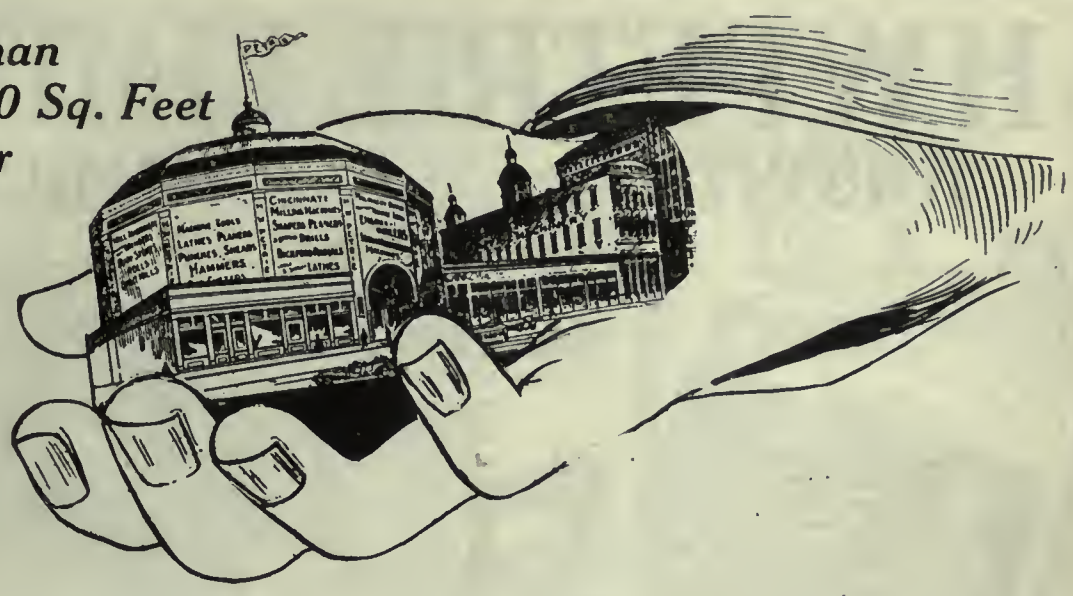
In concluding its remarks the Globe on this occasion said: "This is one of the most extensive machinery establishments on this continent."

What the house of Petrie was to the machinery trade of the Dominion in the early nineties, it remains to-day—Canada's Premier Machinery and Supply House.

H. W. PETRIE LIMITED

TORONTO and HAMILTON

More than 130,000 Sq. Feet of Floor Space



Petrie's Toronto Ware House

Ideal Location Next to Union Station

OUR main warehouse at Toronto is in the heart of the city, next door to the Union Station. We consider ourselves remarkably fortunate in being able to retain a warehouse of such large dimensions in such a convenient spot. Here we have 60,000 feet of floor space devoted to Machine Tools and Supplies for the metal working and woodworking industries.

Then within easy distance of our main warehouse we maintain a large annex at the corner of Bathurst and Niagara Streets. It includes 3¼ acres of yards and 70,000 square feet of warehouse floor space. The floor space in both warehouses thus totals 130,000 square feet.

Our location is of advantage to anyone in Toronto who wishes to inspect our lines, and anybody coming from outside the city is able to step from the train into our main offices and warerooms in two minutes, and it takes but five minutes by car to reach our annex.

You are always welcome at "Petrie's." Give us a call at any time.

24- to 42-inch High Speed Shaft Driven Upright Drilling Machine

Equipped with Patent Geared Tapping Attachment and Variable Speed Motor, this machine offers a practically unlimited range for modern drilling operations. It is standard equipment in many up-to-date plants handling large quantities of high quality work where the "all geared" shaft drive not only assures more power but appreciably reduces wear on the bearings.

Short gears, completely enclosed, provide any of six positive feeds instantly available while our patent geared tapping attachment is the greatest production "accelerator" ever developed. Let us describe it and other features of this famous line.

The Cincinnati Bickford Tool Co.

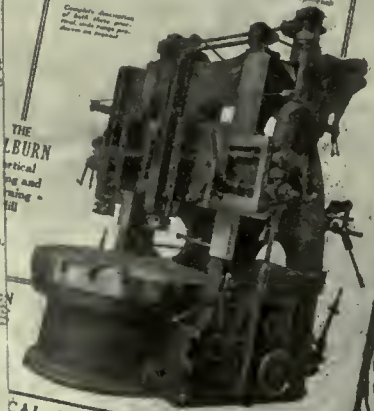
The Cincinnati Gear Cutting Machine

CINCINNATI

COLBURN

THE reputation of Colburn Heavy Duty Machines is based on their power, accuracy and conscientious and thoroughly satisfactory manner in which they solve modern shop problems.

The No. 74 Drilling Machine on the opposite page, for example, drills deep forged connecting rods as the rate of 40 rods—160 holes—per 10-hour day. The two holes are respectively 2.875" diameter, 9 11/16" deep and 3.375" diameter, 2¼" deep—and both holes are drilled, rough bored, faced and finish bored.



CAL BORING AND TURNING MILLS

A Pioneer Machine for a Pioneer Company

The Pioneer Novelty Manufacturing Company of New York City, among the first companies in its field, found a fitting companion in the

THURCO
Die Milling Machine

a pioneer also. The THURCO DIE MILLING MACHINE was among the first, if not the first, of the machines of its type on the market. For over a quarter of a century it has proved its time and labor saving ability to such an extent that it is to-day *standard equipment* in many die stamping industries.

ONE HOLE ONLY is bored in the die, and the THURCO cuts out the entire shape in ONE PIECE.

MINIMUM FILING is required to finish the die, because, with THURCO'S *flexible* but *positive screw feed,* the shape of the die can be followed with great accuracy.

A circular giving complete information will be sent on request.

We are makers of THURCO SAWS and THURCO FILING MACHINES

It Will Pay You to

DIAGRAPH YOUR SHIPMENTS

For Speed— and Insurance Against Loss

A **DIAGRAPH** machine is the cheapest insurance you can buy against lost shipments. The rough abuse acquired through numerous transferring calls for an address that can not be torn or rubbed off through contact. **Diagraph Machines** make permanent, legible stencil markings—a positive insurance against loss. That's why nearly 20,000 shippers in practically every line of business use **Diagraphs** for cutting stencils to address boxes, barrels, bales, crates, stock bins, castings, machine parts, etc.

And then there's the matter of speed. Are you going to let your shipping clerk mark one box by hand in the time that he could address four or five with a Diagraph Stencil? The Diagraph cuts 100 to 120 addresses an hour—about 900 a day—equal to or greater than the speed requirements of the largest shippers in the world.

THE
Oliver of Adrian

For sawing, filing, lapping, keyseating, screw-slotting, and many other operations.

Turning Out Work in One-Half to One-Third the Usual Time

The making of dies, templets and gauges by hand is a slow, tedious, costly operation.

Why stick to this old method of tool making when you can get a machine that will do **better** work in a **fraction** of the time?

The above illustration shows two diemakers at work, one sawing and the other filing dies in the plant of the Robbins & Myers Co., Brantford, Canada. To them, as well as such firms as Brown & Sharpe, Cadillac Motor Co., Studebaker Corp., Ford Motor Co., General Electric Co., Winchester Repeating Arms Co., and thousands of other users, the **Oliver** is daily demonstrating its ability as a great time, labor, and money saver.

Our catalog tells the story. It shows how you can save much of your present die-making costs. Shows all models and describes fully the work they do. **Write for it now.**

"No Time Recorders for me--my employees are on piece work"

This man stands in his own light!

The man who says: "No Time Recorders for me—I don't need them—my employees are on piece work," has no real appreciation of what goes to make up his costs.

He is like some others from whom we get a similar answer when we introduce International Time Recorders to manufacturers. Had he kept abreast of the times he would know, as other manufacturers know, that it is in piece work plants that Time Recording Systems are scoring some of their biggest successes.

The employees' earnings are only a part of production costs. There is interest on capital and equipment, and depreciation to figure. There is factory "burden expense," such as power, light, taxes, heat, repairs, etc. There is the lost time of other employees depending on the work that should have been done by the absentees. And how can you arrive at even "piece work rates" without an absolutely accurate, legible record of hours worked?

International Time Recorders

Then the loss through inferior workmanship caused by piece workers coming late and scamping their work to get enough done—"seconds," damages materials, tools, etc. Doesn't this all cost money? It does. The remedy is the use of International Time Recorders which ensure punctuality and promote factory discipline. International Time Recorders ensure that you get every minute of working time you pay for. Every employee keeps his own time record and knows it is absolutely just and unchangeable.

For bigger production even with a smaller force use International Time Recorders.

Let us send you our latest circular.

"Production good, discipline good, everything running smoothly. Our Bonus System did it."

TIME is the heart, base and root of All Bonus Systems

A Bonus System will work wonders in connection with improving your output, keeping down overhead, getting full value from peak power loads, and in promoting discipline, contentment, and loyalty. It is doing this for hundreds of other firms, why not for you, too? In order to control the basic element of all bonus systems, which is TIME, you should use

International Time Recorders

An International makes every man his own time keeper. The time records are accurate, unchangeable—yet impersonal and impartial. Its constant urge to punctuality and discipline will cut down the daily total of lost working minutes that so often run into the hundreds of thousands and increase the overhead expense. Our Job Time Recorders take care of piece-work operations. Our In-and-Out Dial or Card Records insure punctuality at the daily shifts.

Send for our latest printed matter.

Greenfield

Trade-Mark Reg. U.S. Pat. Office

Plain Grinders

will greatly cut the cost of your small cylindrical work within the limits of 4 x 12 inches. Equipped with small grinding wheels for taking light cuts with great rapidity, they require only a minimum amount of power.

Greenfield Plain Grinders are strong, accurate, medium-weight machines capable of giving any degree of speed without shifting belt or changing gears. They grind small standardized parts with efficiency and dispatch.

It will prove worth your while to investigate their many other money-saving features. Write to-day for particulars of this money-saving grinder.

Greenfield, Mass., U.S.A.

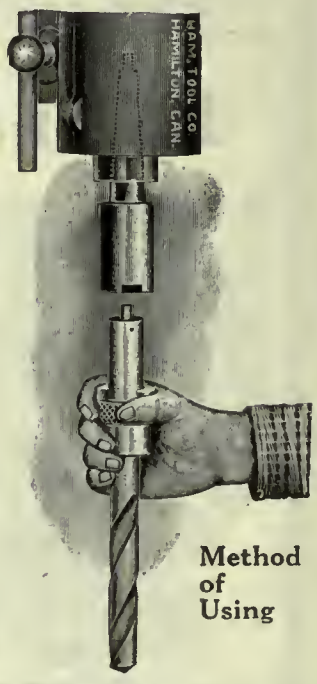
THE BEAVER CHUCK AND COLLET

A Real Time-Saver!

With the Beaver Chuck and Collet you can interchange your drills, reamers, counterbores, etc., **without stopping the machine!** The change is made easily, with the use of hammer, wrench or key. One hand is enough! A self-contained device releases collet and tool instantly.

The Beaver Chuck and Collet converts a single spindle into what is practically a multiple spindle machine. Think of the time you will save! As many tools on one machine as you have operations on any piece of work.

Write for full particulars.



Method of Using

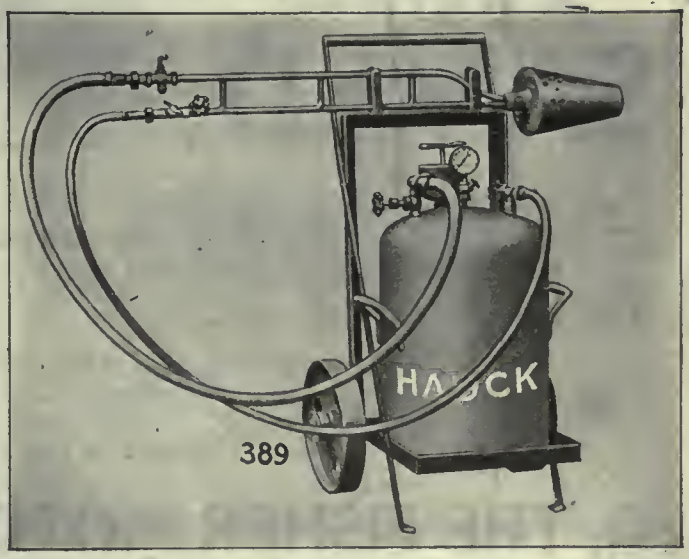
The Hamilton Tool Co., Limited, Hamilton, Ont.

Hauck Burners

Light Instantly, Without Preheating

Illustrated on the right is the Hauck Compressed Air Type Burner. This outfit burns the cheapest grade of crude fuel, kerosene oil or distillate, with compressed air at any pressure from 20 to 100 pounds—**and requires no preheating.**

Built for everyday hard use, these burners are practically indestructible, though extremely light in weight. Flames are steady and easily regulated to any size.



Canadian Hauck Burner Co., Ltd.
PORT HOPE, ONT.

Hauck Burners are made in designs for every requirement of the machine shop, the foundry, the power plant and in apecial designs for individual requirements.. Our Bulletin No. 112 contains complete information; shall we mail you a copy?

New Truths and Old Fallacies

Fusibility of Alloys—*Continued*

One of the best illustrations that we can give of the effect of frictional heat is shown in the test of Magnolia Metal in comparison with a dozen or more of the best known brands of Genuine Babbitt.

This test was made by Dr. Torrey (deceased), then chief Assayer of the United States Mint at New York.

The Magnolia test block was run for eighty minutes with variable loads up to 2,000 pounds per square inch, 1,600 R. P. M. on 5-inch shaft.

Not one of the Genuine Babbitts came within measurable distance of Magnolia, as they ran out in from five to fifteen minutes at loads of 500 to 1,000 pounds per square inch—one reaching 1,400 pounds, but failing in ten minutes. The failure of the Genuine Babbitts was not from lack of quality, but simply because the frictional heat could not be prevented from reaching a destructive temperature, although tested on the same machine and under the same conditions as Magnolia.

Some of these Genuines might have been slightly harder than Magnolia, and Magnolia would have squashed in exactly the same way under the same low stress, had not its self-lubricating quality kept the temperature from rising beyond a safe limit.

At moderate speeds and pressures these Genuines might never have given such evidence of their deficiency, and would have been credited with being as good, if not better, than Magnolia.

This Magnolia quality, as exemplified by this test, shows the saving grace of a low frictional co-efficient and also the futility of mere hardness to save a metal from squashing.

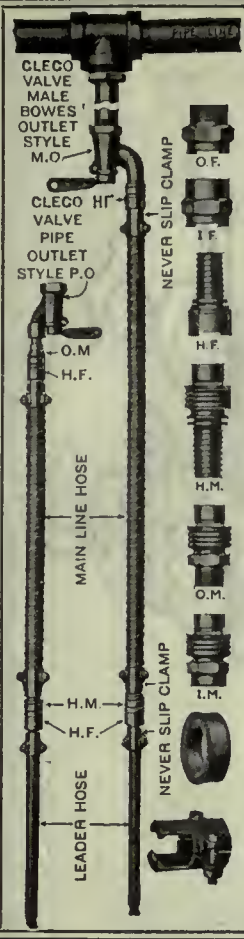
Cleco Pressure-Seated Air Valves

Bowes Air Hose Couplings—Cleco Never Slip Hose Clamps and Cleco Grooved Hose Nipples and Hose Clamp Tool



STYLE O.F. is an Outside Thread Female Pipe End. Made in sizes ⅜-inch to 1½-inch.

STYLE I.F. is an Inside Thread Female Pipe End. Made in sizes ¼-inch to 1½-inch.

STYLE H.F. is a Female Hose End with spiral shank to insert into the hose and has groove for the Never Slip Hose Clamp. Made in sizes ¼-inch to 1½-inch.

STYLE H.M. is a Male Hose End with spiral shank to insert into the hose and has groove for the Never Slip Hose Clamp. Made in sizes ¼-inch to 1½-inch.

STYLE O.M. is an Inside Thread Male Pipe End. Made in sizes ¼-inch to 1½-inch.

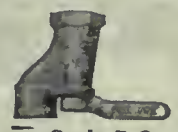
STYLE I.M. is an Inside Thread Male Pipe End. Made in sizes ⅜-inch to 1½-inch.

The Male and Female Ends of Bowes Couplings interchange in sizes ¼-inch to ¾-inch. Sizes 1-inch and 1¼-inch interchange. The 1½-inch ends interchange only with themselves.

BOWES COUPLINGS

Are instantly connected or disconnected.
They are absolutely air-tight under all pressures.
They quickly pay for themselves by stopping costly leaks.
They interchange in sizes most commonly used.
They have no loose parts to be mislaid or lost.
They are made of brass and will not rust.
The U-shaped Gasket interchanges in couplings ¼-inch to ¾-inch.

CLECO VALVES



Style P.O.

Style M.O.

Style A.

Style P.O.—Made in sizes ¼ in., ⅜ in., ½ in., ¾ in., 1 in., 1¼ in., 1½ in., 1¾ in., and 2 in. Pipe Outlets. Inlets are one pipe size larger.
Style A—30° Angle Valves, are made in sizes ½ in., and ¾ in.
Style M.O. Valve—Has 1 in. Inlet and Bowes Coupling Outlet. Connects with Bowes sizes ¼ in. to ¾ in.

CLECO GROOVED HOSE NIPPLES

Grooved Nipples when attached to the Hose with Wire Clamps as illustrated cannot "blow out." Wire clamp tool shown below applies the wires to hose.

The Lightening Hose Clamp Tool illustrated applies wire clamps at a cost of 1½ cents each.

In stock: Riveting and Chipping Hammers, Air Drills, Emery Grinders, Sand Rammers, etc.

Use Annealed Wire No. 14

IMPORTANT:—The Small Leaks in your "AIR LINE" mean serious loss in DOLLARS. Have you any idea of the amount of "Air" wasted in small leaks at your connections? Air Leakage through 1-16 in. opening equals 5.32 cu. ft. per minute at 80 lbs. It will pay you to install Bowes Couplings and Cleco Valves, which will stop costly leaks.

Bulletins Nos. 43, 44, 46 and 47 mailed on request.

THE MODEL HOSE LINE illustrated shows correct styles of couplings and valve to use and proper way to attach the Cleco Never Slip Hose Clamps to Bowes Couplings. No "blow-offs" can occur when "Cleco" Clamps are used.

MATHEWS GRAVITY CONVEYOR

A Necessary Aid to Efficiency

Labor is one of the most expensive items of modern shop operation. Any device which will tend to reduce the amount of labor you require, merits your careful consideration.

Mathews Gravity Conveyor is just such a device. The cost of every bit of work requiring operations by more than one machine costs considerably more than is necessary to produce, if the piece must be trucked or carried by hand from one machine to another. Eliminate the labor expense of transportation and the cost of each piece is appreciably reduced.

Install Mathews Gravity Conveyors. They will solve the problem of transporting your pieces. They will take the work from machine to machine for nothing—gravity does the work!

It will be worth your while—ask us for full particulars. Drop us a line to-day!

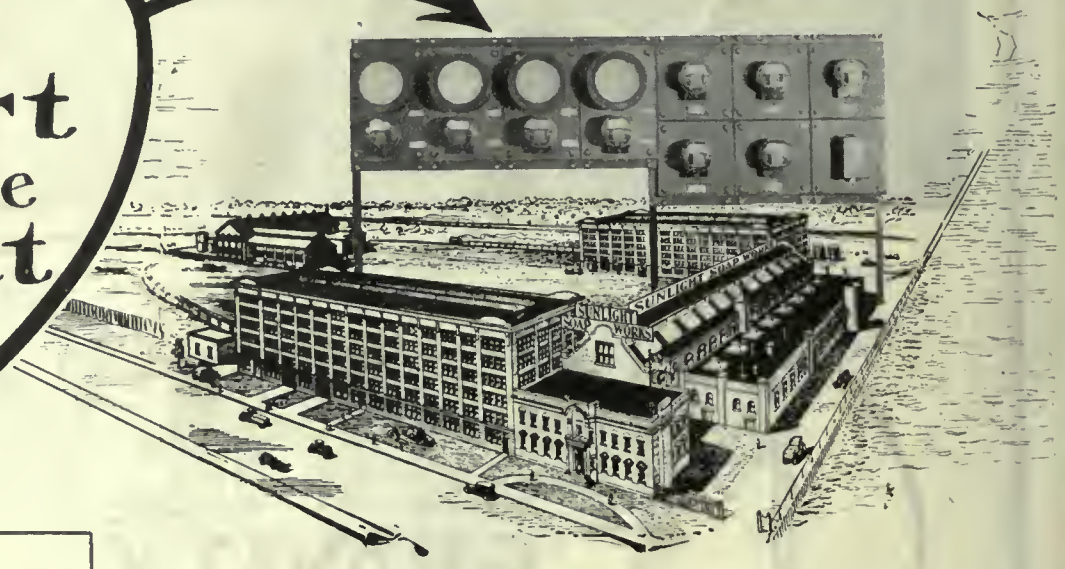
Republic

Flow Meters and

The Heart of the Plant



The Results Secured by this Large British Firm by the Use of **REPUBLIC FLOW METERS** Can be Secured by You

Read the two testimonials herewith. Then tell us how Republic Flow Meters will conform to your plant conditions and save time, worry and expense.

Less Fuel Consumed

The Republic Flow Meters Co., of Canada, Limited, October 12th, 1920.
145 Wellington St. West, Toronto.

Dear Sirs,—We wrote you some time ago, shortly after your Meters were installed, advising that we were getting good results. The installation is now complete and we have many good figures to work with.

We have located leakages of steam which it would have been impossible to discover without the use of your Meters.

Our fuel consumption is being reduced daily and we hope by the end of the year to have yet more complete and lasting results.

The Meters paid for themselves the first week they were in operation.

We would be glad to furnish particulars to any of your customers who may require information.

Yours very truly,
LEVER BROTHERS, LIMITED,
(Signed) James Mess, Works Superintendent.

One Boiler Less Needed

The Republic Flow Meters Co., of Canada, Limited, October 1st, 1920.
145 Wellington St. West, Toronto.

Gentlemen,—In reply to yours of the 29th enquiring as to the results we have had from Republic Flow Meters, I beg to state that since we have had the meters in operation I have been enabled to cut one boiler frou use, and also by discovering leaks in lines, I have been able to carry over the week ends with one boiler instead of two as formerly.

We have been able to make great progress with the conservation of fuel by the application of the meters, and I am convinced that a plant without them cannot be economically run.

I shall be glad to show any person you may refer to me the charts, and prove to them the indispensable value of Flow Meters.

Yours truly,
LEVER BROTHERS, LIMITED,
(Signed) Wm. S. Ball, Power Engineer.

Republic

CO_2 Recorders

Point Out the Path to

Systematic Saving

THE Republic Flow Meter points out the path to systematic saving and tells you what your conditions are in the boiler room, the engine room, and in every department where steam is used.

It is a constant guide to saving, and, once the habit of saving has been acquired, the amount of savings is practically unlimited.

The Republic CO_2 Recorder has been developed to operate continuously under all boiler room conditions, the objectionable features found in all other CO_2 recorders having been eliminated. This enables the operator to observe the conditions of combustion at all times and to obtain the highest efficiency from his furnace—which means less work, less fuel, and less expense.

THE chart shown here demonstrates the relation between the percentage of CO_2 in the flue gases and the heat losses through the smokestack, showing the importance of observing and recording the CO_2 contents in the flue gases.

These curves were prepared by the Bureau of Mines at Washington, and we believe that they are absolutely reliable; the most up-to-date and exhaustive that it is possible to find.

By a reference to this chart it will be seen how the reduction of CO_2 shows the tremendous wastes that are going on in every plant to-day.

What is your percentage of CO_2? If you do not know, then you should know. If you do know, then refer to this chart, find out what your percentage of waste is, and the result, we feel sure, will be that the average CO_2 carried in your plant will be increased at once. **Investigate Republic CO_2 Recorders now!**

Molybdenum Steels

"MOLY"
Our Trade Name for Chrome-Molybdenum Steel

The publicity being given to Molybdenum as an alloying element for commercial steels is pleasing to us in that it serves to direct attention to a very meritorious alloy steel.

The first Molybdenum Steel made in the United States in commercial quantities was produced in our open hearth and electric furnaces. We have made more Molybdenum Steel than any other alloy steel manufacturer in the world.

Our success in making Molybdenum Steels is undoubtedly due to our long specialization in alloy steel manufacture.

PORTER-CABLE

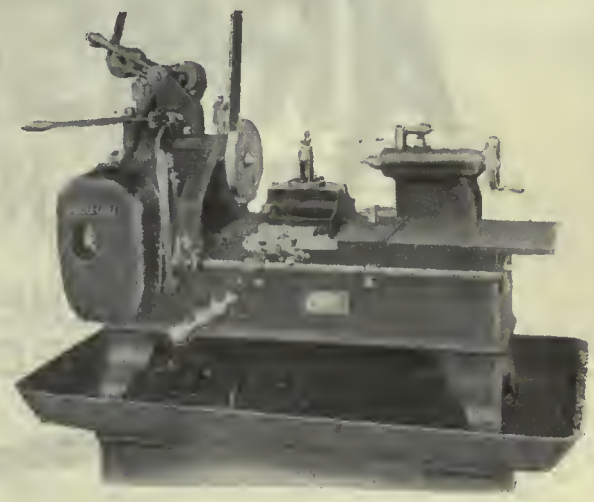
PRODUCTION LATHE

For the Rapid Turning of Duplicate Parts

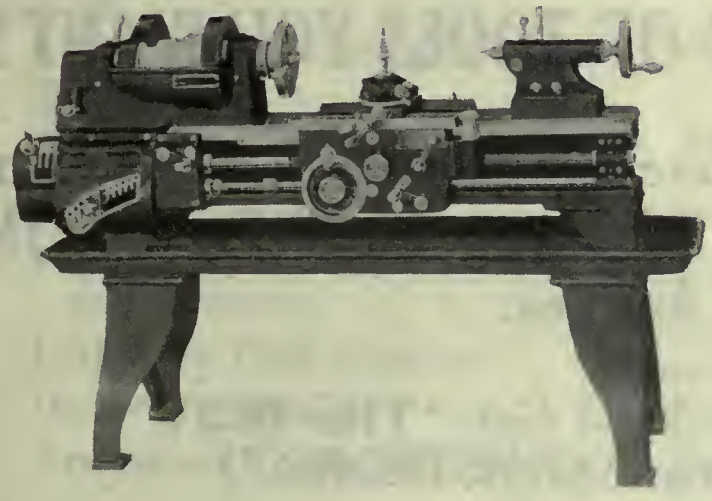
OUR 9-inch manufacturing lathe has speed and power to make it a big producer on a variety of work. It turns four surfaces while another machine turns one. It can roll up chips 5/16 inch thick as fast as the capacity of the cutters will permit.

The small amount of floor space occupied, the comparatively low initial investment and the fact that one man can operate a battery, make it a most profitable as well as economical tool—ideal for second operation work as auxiliary to the big machines.

Spindle takes one-inch bar stock. Carriage travels freely under tail-center. Facing attachment, lever chuck closer, quick return to carriage, unusually rigid taper attachment and other features provide every operating convenience which modern practice demands.



TOOL ROOM LATHE



THIS Quick Change Tool Room Lathe is a model of accuracy, adaptability and convenience. It has a Lead Screw and a Feed Rod. Therefore, the Lead Screw is splineless and not subject to the troubles and inaccuracies due to cutting a spline in an otherwise perfect screw.

Feed Rod is driven from the gear box through a clutch and not affected by side strain or cramp due to rigid connection to gears or gear shaft. It runs in independent bearings. All gears are either steel or semi-steel and important bearings bronze bushed. This machine is guaranteed to bore and turn true within .001".

WALTHAM WHEEL SERVICE IN EASTERN CANADA

FOR three years the Standard Machinery & Supplies, Limited, have successfully represented the interests of the Waltham Grinding Wheel Company, of Waltham, Mass., for Eastern Canada. Its organization knows Waltham wheels and their application to grinding of all kinds.

It is natural that the Waltham Grinding Wheel Company of Canada, Limited, should place the sale of its products for Eastern Canada in the hands of the Standard Machinery & Supplies, Limited, who have so successfully built up their large business on the service they have rendered to grinding wheel users.

The combination of Waltham quality and Standard service for three years has meant much to grinders in Eastern Canada—it will mean even more to them in 1921.

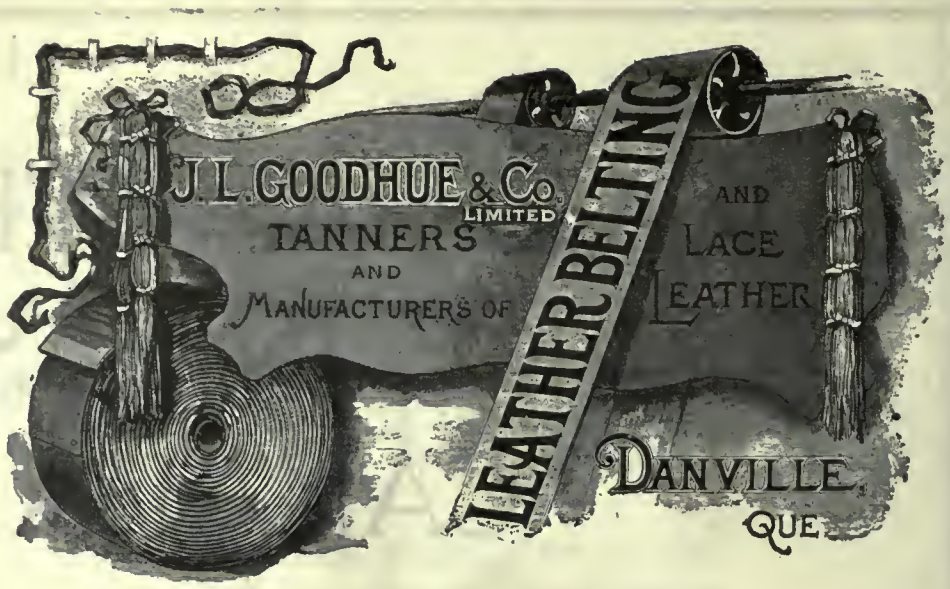
GOODHUE

From the Factory to Your Mill



Good from the Hide to the Finished Belt

A belt is just as good as the hides of which it is composed plus the benefit of the treatment it receives in manufacture.

In the selection of the hides used in making GOODHUE BELTING only the *best* is our aim. This is why, after the hides are well tanned and stretched, the stretcher ends are cut off and only the stretched leather used.

The money wasted in keeping a stretching belt taut is surprising. Because GOODHUE BELTS are practically stretchless, they save most of this money.

Our three brands: "Extra," "Standard," and "Acme Waterproof," will solve your belting problems. Write for full information and prices.

By Service and Results the Morse Rocker Joint Silent Chain Drive has won recognition as the World's most efficient and durable power transmission.

Are you looking for improvement in power transmission, the saving of fuel, the saving of floor space by short centres, fixed speed ratios, improved quality, increased production, lower maintenance costs, longer life and dependability, the increase of profits now lost through slipping belts?

What more positive testimony of efficiency and durability of Morse Drives could be given than the fact that so many leaders of industry and engineers of prominence have specified Morse Rocker Joint Silent Chain for their Power Transmission?

MORSE CHAIN COMPANY ITHACA NEW YORK

HIGH SPEED RIVETING HAMMER

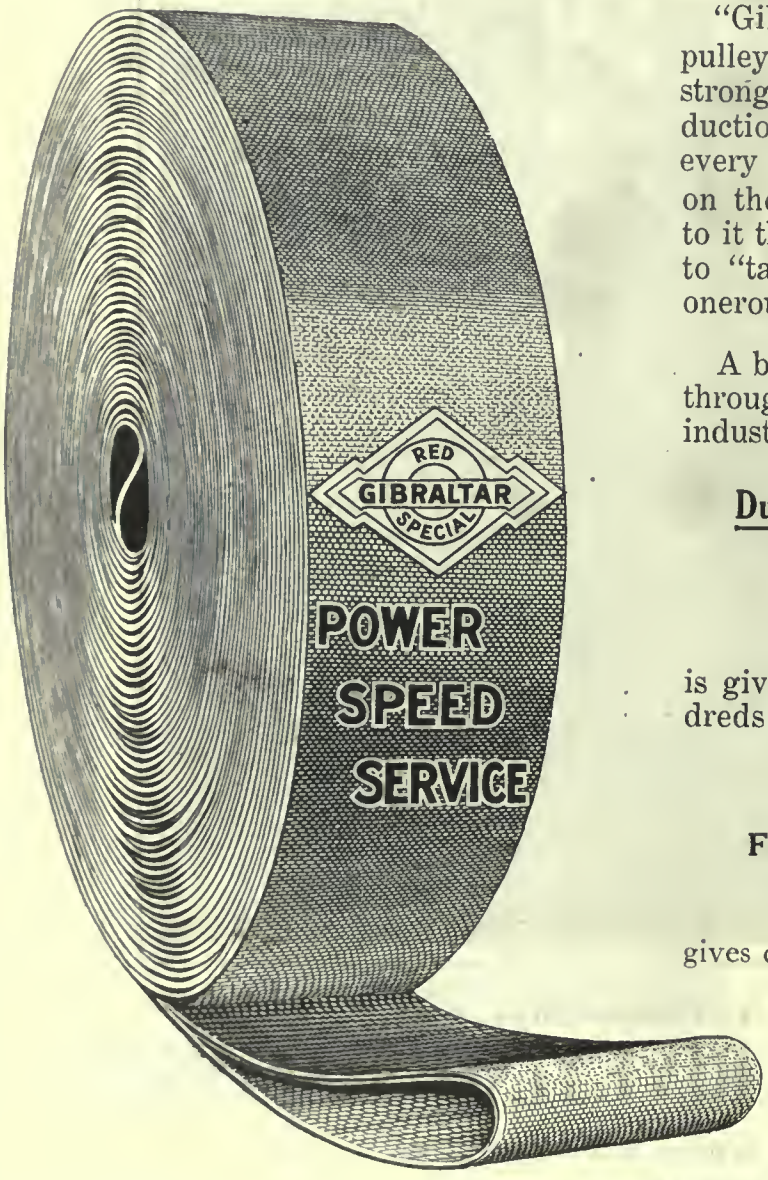
"PATENTED"

AT THE ROBBINS & MYERS PLANT, BRANTFORD, ONT.

This Canadian plant is a branch of the famous Robbins & Myers Company of Springfield, Ohio, one of the largest manufacturers of motors in America. The Canadian plant is finely equipped to take care of domestic and export trade, and efficient and economical production is carried to a fine point. Only the best of machine tools are used. Included among these tools is the High Speed Riveting Hammer.

HIGH SPEED HAMMER COMPANY, Inc.

ROCHESTER, N.Y., U.S.A.



"Gibraltar RedSpecial" Belting
--Cuts Down Producing Costs--

"Gibraltar RedSpecial" Belting is pulley-gripping, non-slipping, pliable, strong. It cuts down the cost of production by faithfully transmitting every vestige of power and keeping on the job. There is so little stretch to it that users tell us they haven't had to "take it up" in several years of onerous service.

A big percentage of the orders going through the factory are repeats from industries which have tried its worth.

Dunlop "Gibraltar RedSpecial"

Water Hose
Air Drill Hose
Steam Hose

is giving highest satisfaction in hundreds of plants the country over.

Dunlop Packing

For All Purposes and Every Condition of Service

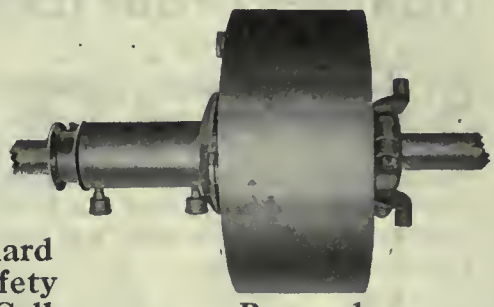
BERNARD

Transmission Appliances

Bernard Safety Collar



Bernard Friction Clutch

You should adopt the Bernard Friction Clutch—built on the most advanced principles, safe, simple, reliable and inexpensive.

Bernard Wood Split Pulleys

Bernard Pulleys are economical Pulleys. Their durability enables them to stand up under the most severe working tests.

They have demonstrated their superiority in hundreds of Canadian plants. They are lighter than solid, split iron or steel pulleys, and thus permit the use of less expensive shafting and hangers. They put less weight on bearings, reduce friction, and save power. For economy and efficiency in the transmission of power, use Bernard Wood Split Pulleys.

STELLITE

Not Steel—but its Master

STELLITE Tools are a permanent guarantee of longer service, quicker work and better work. Stellite tools can be worked faster than high-speed tools, and can take heavier cuts. Stellite tools last longer between grinding.

The manufacturer who seeks higher shop efficiency sees and appreciates Stellite Superiority—a metal harder than steel, of high tensile strength, capable of doing more work than high-speed steel, and doing it more quickly and economically — not steel, but the master of steel.

STELLITE is a cutting metal that cannot be annealed, tempered or heat-treated. It resists oxidation. At red heat, when high-speed steel tools break down, Stellite tools cut at their best. The hotter they get up to 1800 F. the tougher they get, and the longer they last. If you would have your shop produce its maximum, at a minimum of expense, use Stellite tools.

THE MASTER METAL

Schieren's "DUXBAK" BELTING

Wherever the wheels of the world's varied industries hum you'll find SCHIEREN'S DUXBAK BELTINGS transmitting the power efficiently and faithfully year in and year out.

When it comes to selecting belting that is capable of resisting the effects of water, machinery oils, and acid fumes, you want DUXBAK WATERPROOF—the most widely used belting in the world.

In mills, shops, factories and other places where the belting must transmit the load continuously, and "stand-up" with minimum expense —use ROYAL EXTRA.

For belting that is extremely pliable, impervious to steam and water, and particularly adaptable for use on small pulleys running at high speed—DUXBAK NUTAN is unequalled.

In fact, there's a grade of SCHIEREN DUXBAK BELTING to meet every belting need.

The Schieren Trade Mark and the Chas. A. Schieren Company signature appears on every ten feet of DUXBAK BELTING—your guarantee of genuineness and service. A service it will pay you to investigate.

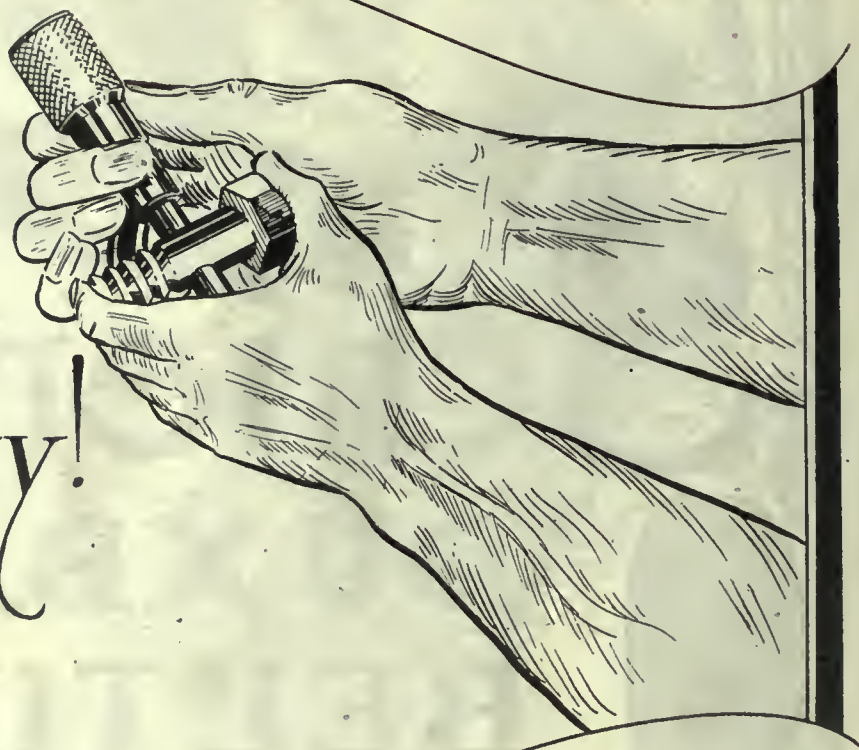
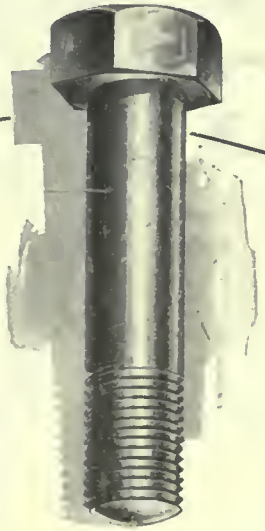
GALT SCREWS

for Accuracy!





TRY a dozen or more Galt Screws of any size with a micrometer gauge. You will be struck with their precise uniformity of size. What does this accuracy in Galt Screws mean to their users? It means that they can always be depended upon to fit! Screws that always fit save a lot of time, trouble and money.

It is the dependable accuracy in Galt Screws that has brought them into wide demand for the building of machine tools throughout Canada.

TO THE MANUFACTURER:

We furnish accurate and therefore interchangeable parts, whether it be Cap and Set Screws, U.S.S. or Plain and Castellated S.A.E. Nuts, Taper Pins, or the more difficult automatic parts for engines, transmission and axles. Our facilities for doing secondary operations, such as drilling, milling, grinding, case-hardening and heat-treating are up-to-the-minute.

McKENZIE Improved

15" Back Geared Crank Shaper

"This new 15-inch Shaper recently placed upon the market by the D. McKenzie Machinery Company, Guelph, has several new features and improvements over the machine built in the past.

The New Extension base affords a much larger foundation for the machine, which is provided with a supporting leg always directly under the weight of the table so that the weight is evenly divided at all times. The Box Table can be removed and the work bolted to the saddle. The Screw for raising the cross-rail is fitted with ball bearings. The Vise Jaws have steel faces with circular graduated base and is arranged so that it will swivel and hold firmly at any angle. The Cone Pulley runs on a sleeve-journal bearing. The Ram has square slides and is provided with felt wipers. The extreme length of stroke is 17" and is adjusted from the operating side of the machine. The Tool Head is fitted with a tapered gib and can be tilted to any degree. All Feeds have graduated collars.

The D. McKenzie Machinery Co.

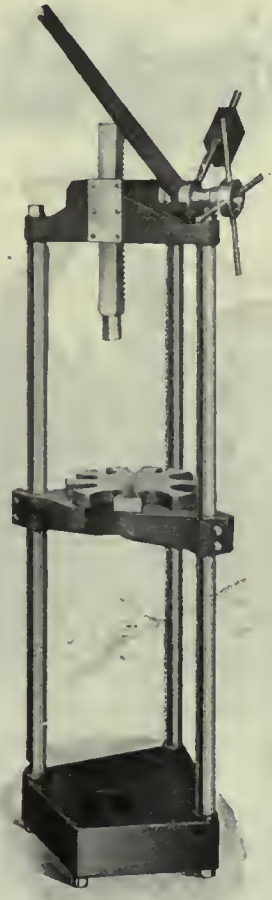
Guelph, Ontario

The NECO ARBOR PRESS

The Powerful "three point" construction permits the maximum of strain with perfect alignment.

The Ratchet Feed with the long leverage giving unexcelled power, together with the automatic release, obtains easy and efficient operation.

Capacity, 3 tons
Clearance, 16 inches
Floor space, 20 inches.



Patents Pending

The Adjustable Table and 36-inch range give it an unusual capacity for service.

Its design and construction are up to the standards and advancement of all "NECO" production where Merit and Service are paramount.

Openings in dial for nine sizes of arbors up to 3½ inches.

We do not put all the strain on one tooth of the ratchet—We put the strain on all the teeth all the time.

THE "NECO" ARBOR PRESS

meets the requirements of the most exacting shop practice where efficiency and production count. Its sturdy, rigid construction and wide range of productive capacity are appreciated by users who know and want practical appliances. It is one of the most useful units of modern shop equipment. Just the thing for the Auto Repair Shop. Price $125.00.

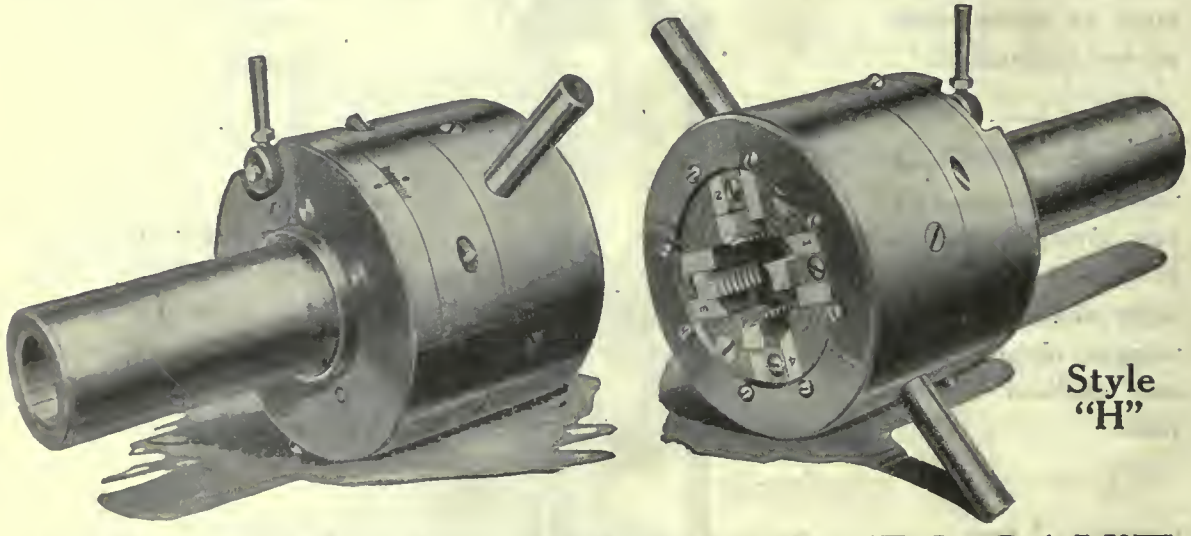
MODERN
Self-Opening Die Heads

(One Type - Two Styles - 17 Sizes)



Style "H"

THEY HANDLE JOBS OTHERS CAN'T

Everywhere you find Moderns on difficult jobs. "Moderns" are almost daily supplanting other types because of efficiency on hard to handle work.

WHAT'S THE SECRET?

The ability of Modern Self-Opening Die Heads to do work not possible for others is largely due to "Modern" distinctive design, although superfine workmanship is entitled to some of the credit.

Chasers in Modern Self-Opening Die Heads have ample and mechanically correct support. Users are not subjected to the annoyances of chasers shifting position during work. They will not "rock," "cock," or "bell at the mouth."

Based on record of accomplishment we've no hesitancy in claiming that Modern Self-Opening Die Heads will produce accurate, uniform threads the longest time without repairs.

Moderns have numerous mechanical advantages.

Send for complete technical bulletin, and study the reasons why Modern is preferred in the most exacting plants.

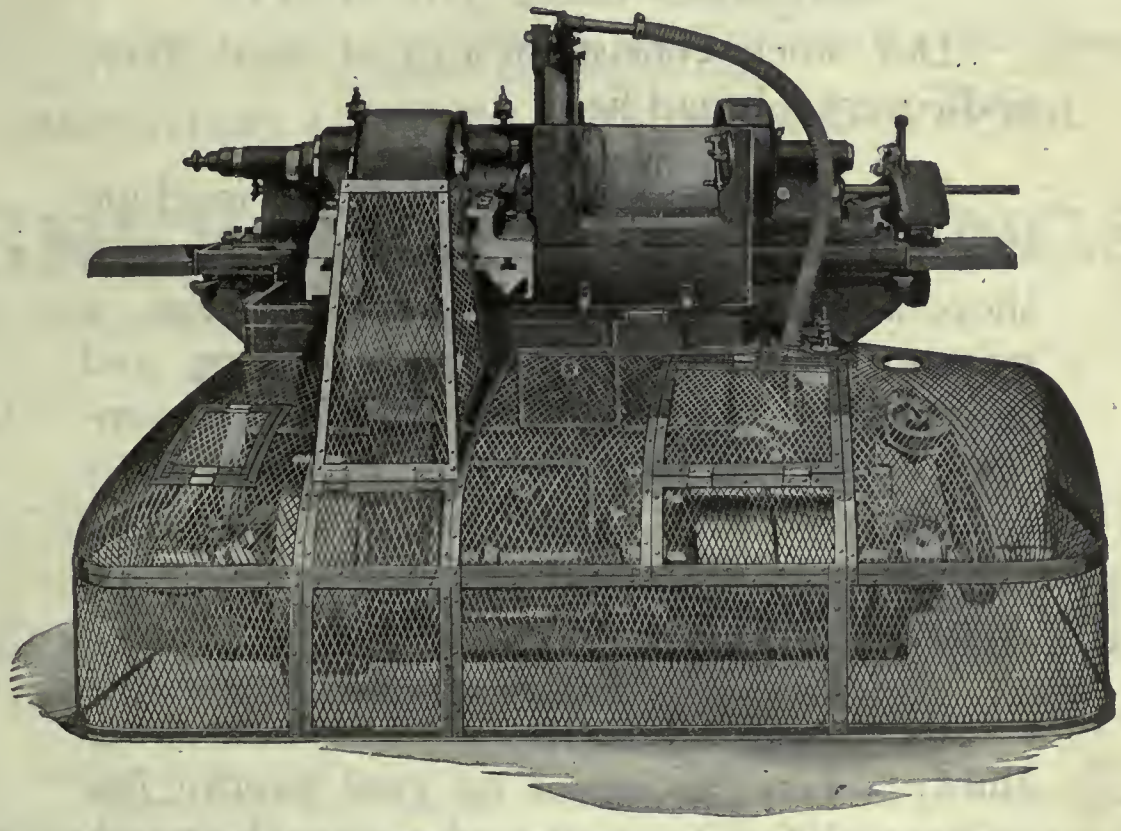
MODERN
Plain Grinding Machines

(8 Sizes -- 8" x 18" to 16" x 60")



ANOTHER SUPERIORITY FOR "MODERN"

Now Fitted With Perfected, Open Vision Guard

The new guards which are now fitted to all Modern Plain Grinding Machines are a great improvement over the heavy, cumbersome, cast iron guards in general use. They are light, strong, safe, and efficient. They are in meshlike construction of expanded, or perforated metal which affords an almost unobstructed view of all moving parts. Meets the most rigid requirements of all safety laws. Our technical bulletin will explain fully how one of our eight sizes may be adapted to your use.

If what you need is not advertised, consult our Buyers' Directory and write advertisers listed under proper heading.

From a Needle to an Anchor

or

From an Ounce to Ten Tons

is indeed a wide statement and an achievement we would be proud to proclaim if it were a fact. But we have only been in the business fourteen years and any reasoning person does not need to be told that it would require the effort of several lifetimes to build an organization capable of substantiating such a claim.

We Want Your Business

which demands that we have your confidence. So we will only say that we are prepared to give you a service (Quality, Delivery and Price) on your

REPETITION, LIGHT TO MEDIUM WEIGHT, BENCH AND FLOOR

GREY IRON CASTINGS

that will place you permanently among our supporters and friends.

A TRIAL ORDER is Our Only ARGUMENT

Send us your patterns and specifications and be convinced to your continued profit.

Do Your Castings Cost Too Much?

A rearrangement of your patterns might cut their cost 25%; a different method of molding them might double your production at no increase in molding cost.

Do You Intend to Build Some Machine

or produce some article which will require a large number of each separate casting? A proper arrangement of your pattern—with the correct method of molding it—is the first step toward bed-rock cost production.

Do You Need Some New Patterns?

Send us a sample, blueprint or sketch for advice. It won't cost you anything. If our advice commends itself to you, it is only fair to assume that our work will be equally satisfactory.

We do pattern work, as an aid to making castings, and it is not to our advantage to advise a hundred-dollar pattern where a cheaper one will deliver the same casting results. Neither would we be a party to your having an expensive plate made with two pieces on it, where you could get six at no greater molding expense—which we have seen done. But we will tell you EXACTLY how to arrange your pattern to get the lowest casting cost with the minimum expense for pattern equipment.

WE SPECIALIZE ON REPETITION CASTINGS

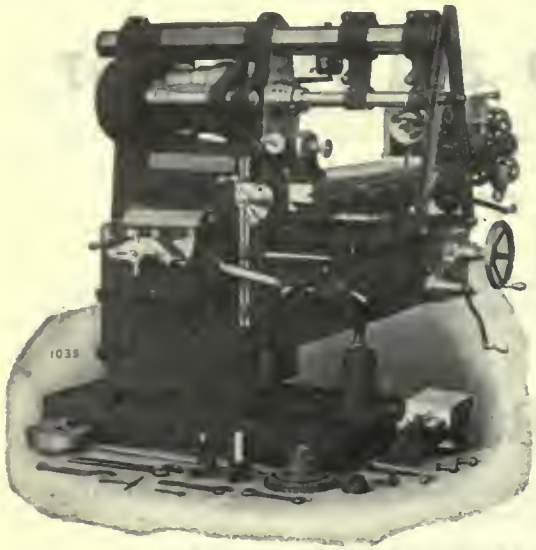
The knowledge gained in twenty years of practical experience on these problems, and our entire equipment is at your service in the effort to obtain BETTER CASTINGS, CHEAPER.

THE TRADE K A T MARK FDY. The Katie Foundry
Galt, Ont.

We are in a position to do turning, boring, drilling or other semi-finishing operations on castings supplied by us.

We have for our and your requirements, a large stock of assorted White Iron Stars, suitable for light agricultural to medium weight machinery castings, while they last, at 8 cents per lb. F.O.B. Galt.

If interested tear out this page and place with letters to be answered.



One of our cone-driven Universal Millers. We make 8 corresponding single pulley type machines.

One of our five sizes of single pulley type, vertical Millers.

One of our 8 high power single pulley plain Millers. We also make 4 cone driven plain machines.

THE Manufacturer who is looking for any one specific size and type of Milling Machine, can exactly satisfy his need from the line of Cincinnati Milling Machines. Included is every commercial size—from 18 in. table travel to 50 in. table travel—from 1 h.p. normal capacity to 20 h.p.—from 1,450 lbs. net weight to 11,000 lbs.—and between these two extremes, 27 sizes and styles of Horizontal Millers. In addition to that a full line of Vertical Millers and Automatic Manufacturing Millers.

You will grant that from such a complete line, you can fill your shop's needs in Millers as perfectly as a plug gauge fits its corresponding ring. A few of them are shown on this page. All of them have won the highest reputation everywhere. Complete details are given in our literature, which will be sent to anyone who is interested.

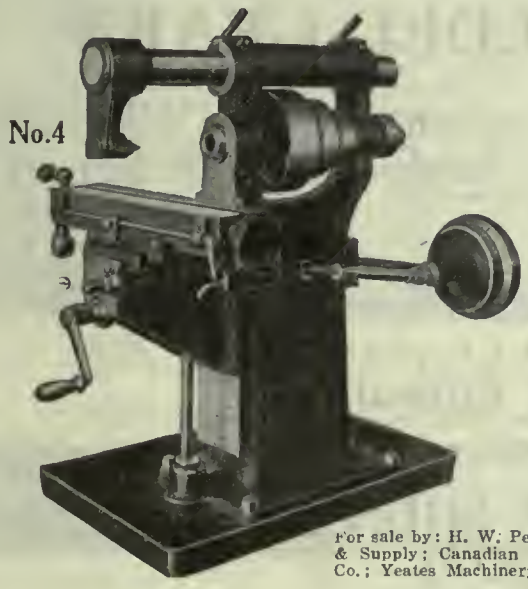
Burke

Bench Milling Machines

No. 3

Accurate, Convenient and Economical!

THESE handy, compact little machines will handle much of the work usually done on the large millers. Their strong construction and lack of all unnecessary parts make them extremely popular. They work accurately every day in the year and their high efficiency is maintained throughout a longer period than that of the average mlling machine. From the standpoint of economy it will be much to your advantage to investigate these Burke Bench Millers.



No.4

Burke Bench Miller No. 3

This accurate little machine will soon pay for itself in the variety of jobs it will handle. Will take care of much of the work usually done on the large machines. Fitted with slotting attachment, vertical milling attachment, index centres—either stationary or tilting heads, etc.

Burke Bench Miller No. 4

Another efficient, compact machine that should be in every workshop. Longitudinal table feed 8". Traverse feed 3". Maximum distance between center of spindle and table 8". Attachments same as furnished with No. 3 machine.

Let us explain further the possibilities of a Burke in your plant. Catalogue of Milling Machines, Drill Presses, Tapping Machines, etc., on request.

A Few Facts About Liquid Air Service

Liquid Air Service Department is composed of men who are specially selected for their expert practical and technical knowledge of the Oxy-Acetylene Process. They are at the disposal of all our customers to whom their services may be of use for which no charge is made and no obligation incurred.

In addition to our eight factories, five Distribution Stations have been established at St. John's, Nfld.; Sydney, N.S.; Quebec, Que.; Ottawa, Ont., and Windsor, Ont., respectively, for an immediate supply of Oxygen and Acetylene to consumers located in these Districts, with a minimum of freight rates and the elimination of delays occasioned by long distance haulage.

At the present time, as in the past, L'Air Liquide is in a position to give service which is unassailable.

Dominion Oxygen is available for immediate shipment

CANADIAN industry is now assured of a continuous and easily accessible supply of the highest grade oxygen. The completion of the first four of the Dominion Oxygen Company's distributing stations makes manufacturers throughout Canada independent of long distances and uncertain transportation. A completely stocked Dominion Oxygen center, within easy railroad or motor truck delivery distance of your plant, is ready to start your oxygen shipment on the day your order is received.

The Dominion Oxygen Company, Limited, through its constantly increasing facilities for greater production and faster distribution, is now in a position to give you twenty-four hour service.

An unfailing supply of pure oxygen within easy reach, cylinders of a new and lighter type which make worthwhile savings in transportation and handling charges, a liberal cylinder loan policy backed by courteous and prompt attention to your order is our conception of service.

THE WELD THAT HELD

Do you know that welding by the electric arc process is lower in cost than by any other method? Practically every industry engaged in the metal trade can utilize electric welding to advantage.

We are prepared to handle all kinds of production welding, boiler repairs, steel tank construction, rebuilding worn or broken shafts, reclaiming defective castings, and rectifying errors in machining.

Our facilities enable us to take care of the largest welding operations.

Let us demonstrate the economy of ELECTRIC WELDING.

All Work Guaranteed.

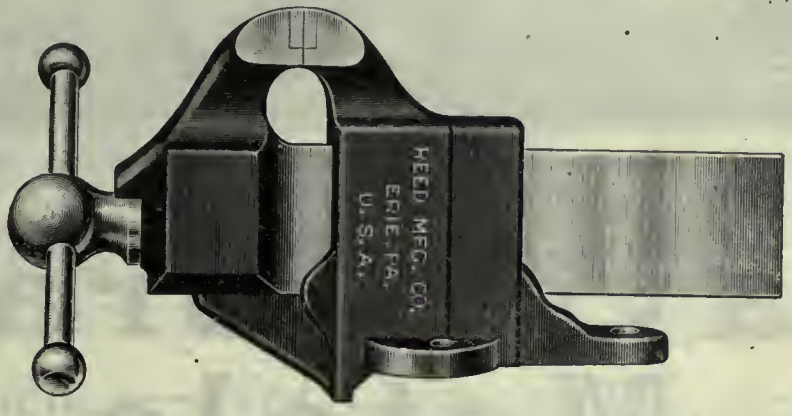
REED VISES

Strong---Rigid---Will Not Break

—They Give the Service—

Machinists' Vises

Filers' Vises



Coach Makers' Vises

Pipe Vises

For Twenty Years Preferred Because of Unequalled Quality

Reed Vises have many exclusive features, each offering an advantage to the purchaser.

May We Send You Proof
Of Reed Superiorities?

5 Helpful Pamphlets

1—Primary Function of a Vise.
2—Have You Enough Vises?
3—Rigidity (As applied to Vises).
4—Are Yours Heavy Enough?
5—A Vise of Pure Gold.

These pamphlets deal with principles which apply to all makes. Write for any or all of them.

Reed Vises are the best obtainable. Twenty years is a conservative estimate of the average life of a Reed Vise. Do the kind you use last that long, and give satisfactory service all the while?

Reed Vises Sold in Canada by 18 Dealers

—Dealers are located in the following cities:—

Calgary, Halifax, London, Montreal, Ottawa, Vancouver, Winnipeg, Toronto, Edmonton.

May we give you the name of the dealer nearest you?

Reed Vises are guaranteed throughout. The difference in cost between a Reed and any cheaper kind isn't worth a second thought. Any kind that costs less will deliver enough less service to more than offset the difference in cost.

Complete catalogs sent upon request.

Science—Not Custom Developed Goodyear Steam Hose

Goodyear has done away with the ills to which wire-bound steam hose falls heir—by developing a hose with fabric of such strength that wire winding is not necessary; a rubber cover of such toughness that no other protection is needed.

No more hose choked by bent wire—blistered by unequal expansion—too hot to handle—clumsy and hard to cut into shorter lengths.

Goodyear tackled every kind of hose in the same way. Research to find out what industrial hose lacked and what industry needed. Experiment to solve those problems.

One by one, Goodyear has produced new types of hose to meet specific needs better than those needs have ever been met before.

The expense of *your* steam, air drill, water or fire hose *can* be reduced. Goodyear data will prove it and a Goodyear trained man will show you how. No obligation on your part to have him call. Phone, wire or write the nearest branch or Goodyear Mechanical Goods Service Station.

The Goodyear Tire & Rubber Co. of Canada, Limited

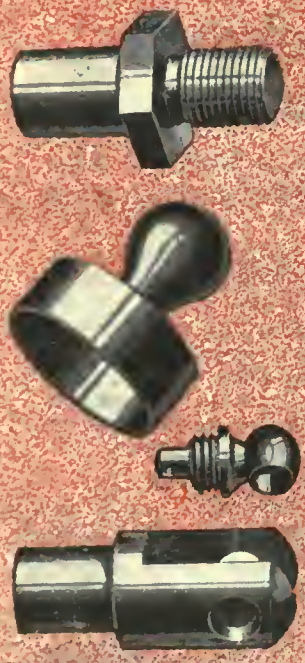
SERVICE

NAMCO

SCREW MACHINES - DIES & TAPS - SCREW MACHINE -PRODUCTS-



Special Screw Machine Product up to 4" diam

Those who grow weary of "service talk" have been frequently misled by offers of a good product and prompt delivery.

Our customers know that NAMCO Service has a deeper meaning, a more profitable value to them.

For example—every year a fair percentage of our Automatic and Auxiliary machines go into our own shops.

Every month more NAMCO Self-Opening Dies and Collapsing Taps are added to our operating equipment.

Every week thousands of Standard Screws, Nuts and special parts from our Product Plant find use in the new machines of the same kinds that make them.

What does this mean to you? Simply this: We believe that your problems of accuracy, output and low cost of manufacturing are much the same as ours. And the experience gained by taking our own medicine is really the *service* that customers have a right to expect. They get it, and that is why NAMCO Service means so much to them.

Let us prove what it will mean to you.

VOORHEES RUB-STEEL VALVES

"The Valve With A Backbone"

GRADES

Superhot
For Boiler Feed Oil, Acid, Ammonia, Vacuum Returns, Locomotive Boiler Washing, Marine Air Pumps, Gasoline—highest temperature within 250 degrees.

Red Condenser
For Highest Vacuum, Excessive Grit, Pottery Slip, Soda Ash, Condensing and Brine Pumps where moderate pressure is applied and heat is within 110 degrees.

Standard
For Elevators, Water Department services and Clear Water not exceeding 160 degrees. Wherever high pressure is applied without excessive temperature.

Special Soft
For Water Department service, Fire Pumps, Bilge Pumps, moderate grit and in temperatures not exceeding 120 degrees.

Cover Every Possible Pumping Condition

The strong, pressure-defying steel plate—the "backbone" of the "Rub-Steel" enclosed in tough resilient rubber is to-day's greatest achievement in valve construction. This metal disc is firmly and permanently united with the rubber surfaces. The result is a valve that will withstand high temperatures and pressures without warping, buckling or dishing.

Send for sample—it will convince you that Rub-Steel is the best valve.

Rockford

Horizontal Boring Machine

For Heavy Duty

THIS type of Rockford is unexcelled for continuous production. It is of the single end type equipped with two spindle drive head and indexing table, complete with fixtures, cutters and line bars. Its construction insures continuous production of the first quality and continued accuracy. There is no machine which so well meets the requirements of accuracy, production and adaptability as does the Rockford.

The drive is directly by motor with interchangeable pick-off gears for speed changes. The table may be indexed 180 deg. to bring both fixtures in turn into operating position. One fixture is being loaded while the other is in operation.

Complete equipments are a Rockford specialty. This equipment is the choice of most automotive engineers for solving their boring problems.

VICTOR

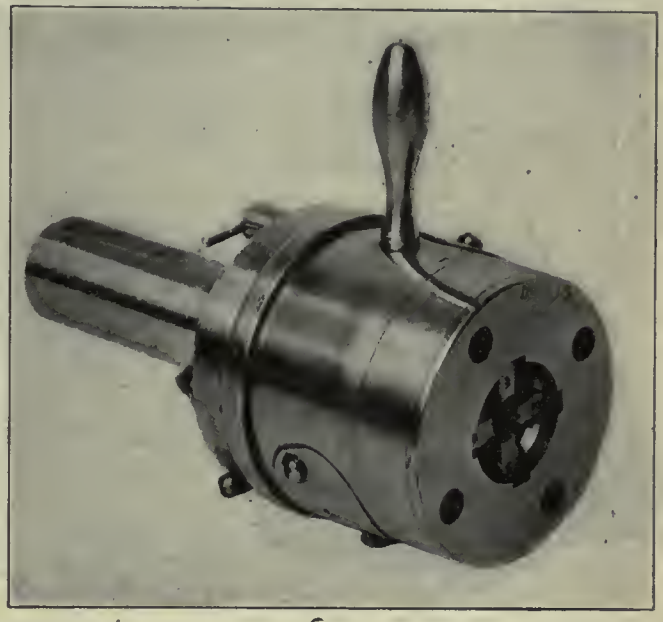
Self-Opening Die Heads—Collapsible Taps

For Clean, Smooth Threads and Lower Costs

VICTOR SELF-OPENING AND ADJUSTABLE DIE HEADS open automatically when travel of turret is stopped, or by means of an internal trip, can be adjusted to cut 1-32″ over or under size. Head is completely enclosed, no dirt can enter.

Proof of their superior service is given by the following observation of a user:

"The work done by these chasers has been so superior to anything we have had in the shape of die work that we feel like expressing ourselves so that you may feel encouraged to go further."



VICTOR ADJUSTABLE AND COLLAPSIBLE TAPS are adjustable for wear, are long lasting, and invaluable in bulk production. Released by a trigger when bottom of hole has been reached; they save time and avoid spoiled threads.

More proof of "Victor" merit:

"Two operations and half another completed in the time our old taps took to do one; that, I guess, is why we continue to use your Victor Collapsible Taps," writes an enthusiastic customer.

The Victor line of thread-cutting equipment is complete; styles and sizes to meet all needs. Write for full line of thread-cutting literature.

THE GARVIN MACHINE CO.

Builders of Machine Tools since 1865

The end of our nose—

If the exchange of Garvin built machine tools for some of your money were our only aim, you might well say that the tip of the nose was the limit of our vision. Rest assured it is not.

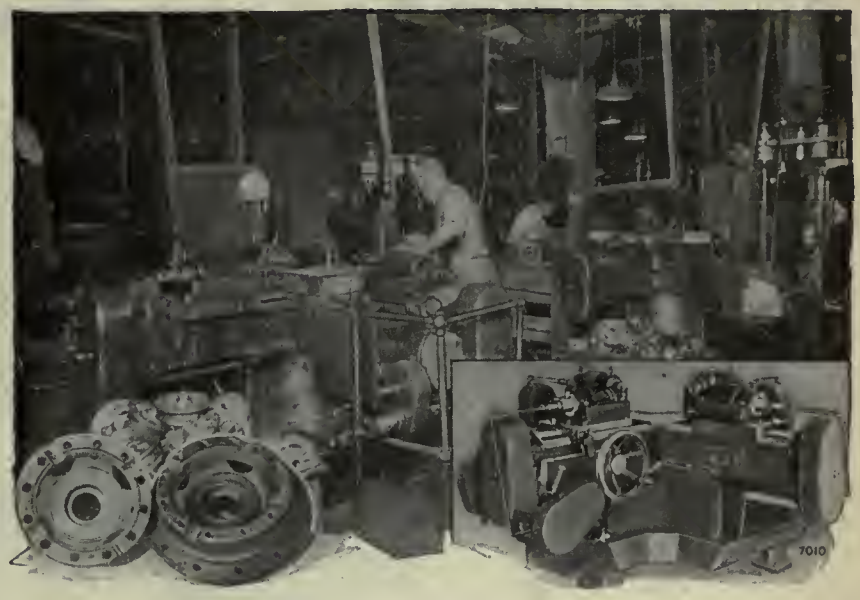
In fact we would rather have a man come to us and say, "Here's my problem—what'll I do?"

That's the real foundation of the business we've long been building, —"Service" in the way of drawing on our fund of information that has come with years of constant study.

And we are just as free to say, Mr. Man, you ought to put in a Thus and Such as we are to point out the need for a machine of our own make. We like to feel that our friends can come to us for real advice—and they do.

It doesn't cost you anything to find out about Garvin Service in the way of advice on machine shop problems—we'll feel honored at your asking.

H. R. Garvin



These Two Garvin No. 2 Four-Head Right-Angle Drilling and Turning Machines

are increasing production at the Brown-Lipe-Chapin Company's Plant

Equipped with combination drills and reamers, these Garvin No. 2 R.A.D. Four-Way Drilling Machines are drilling and reaming spider holes, 4 at a time, in differential cases. Although this is a particular job which demands accuracy, as the holes must be exactly at 90 degree angles and to within .002 limits, they have never failed to make good since installed more than 2 years ago.

These machines are ideal for manufacturing automobile differential parts. They embody a strength and accuracy, maintain their alignment, will not spring under heavy cuts and are rapid and easy to operate.

It will prove to your advantage to send for our 340-page Garvin Catalog fully describing the Garvin No. 2 R.A.D. Four-Way Drillers and our many other machines.

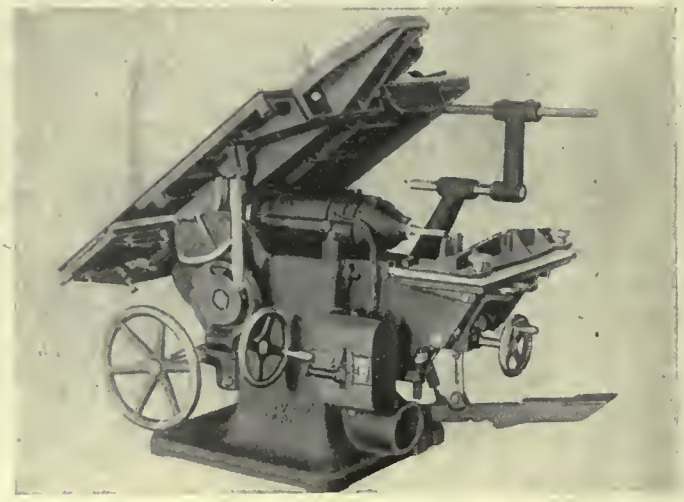
The OLIVER
No. 80 Variety Saw Bench

Either Belt or Motor Driven



View of Self-contained Motor-on-Arbor Machine

This New Labor-Saver Commands Your Attention

IF YOU have a variety of work, the **Oliver No. 80** is the machine you should have in your shop. It will save labor, time and expense, and the fact that it is an **Oliver** is proof of its general efficiency.

The machine is designed and built strictly to meet present-day requirements in the production of variety woodwork, wood patterns, furniture, automobile bodies, carriage bodies, agricultural implements, talking machine cabinets, and other high-grade woodwork. It will do ripping, cross-cutting and dadoing quickly and efficiently. Cuts a perfect mitre and measures an angle instantly and accurately. It will cut off a length or rip to width. No calculating required to do this, neither does the operator have to refer to a rule.

The construction is rugged throughout and all necessary attachments such as mitre cut-off gauge, etc., are provided. Two types of tables can be furnished, plain and universal.

There are many other features of the **"Oliver" No. 80** you should know about. Send for complete description.

Before placing your next order for Pattern Shop Equipment, Woodworking Machinery, or Engine Lathes, you should investigate the "Oliver" line.

Oliver Machinery Co., Grand Rapids, Mich.

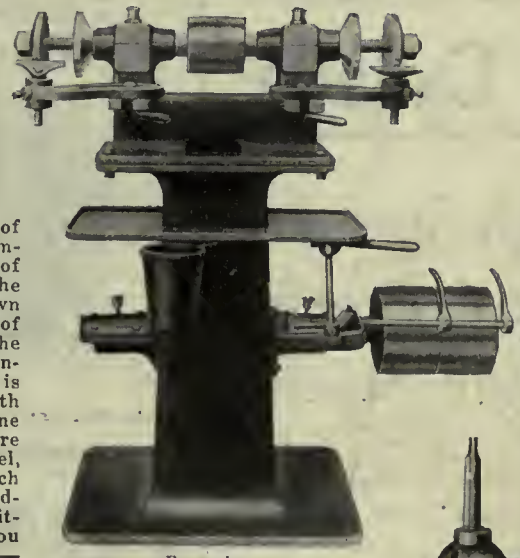
SAINT LOUIS

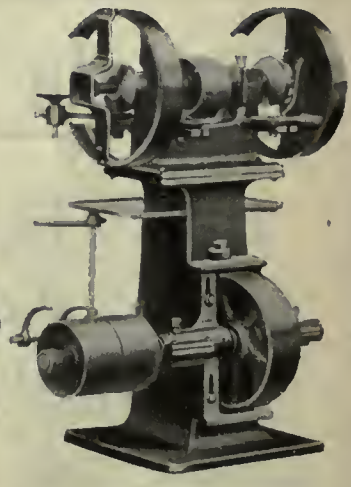
Self-Contained

Countershaft Grinder

SMOOTH running of wheels is an important advantage of these grinders. The belt strain being down against the body of the machine gives the wheels a smooth-running motion, which is impossible to get with this class of machine belted up. Arbors are of 40% carbon-steel, thread two-pitch coarser than standard. Has other profitable advantages you should know about — send for full description.



Front view



The Saint Louis line is carried in stock by leading dealers in Canada, England, France, South Africa, New Zealand, and Japan.

SAINT LOUIS TAPPING MACHINE

Actuated by foot; both hands being free to handle work makes this machine a rapid producer. Made in two vertical sizes, and one horizontal size.

Saint Louis Tapping Chuck—all steel and bronze. Very durable. Four sizes.

Murchey Taps

Murchey Collapsible Taps Never Strip Threads

As soon as the tap is tripped, the chasers collapse—and the stress of the heaviest work will not make them collapse before the proper time.

The chasers are adjustable to compensate for any wear, thus enabling the tap to maintain its minute accuracy.

For convenient, quick-acting operation and general all-round dependability, use Murchey Collapsible Taps. They are built for service—and they give it.

PACKINGS

Take packings—rod and sheet—away from the industries, and even the most inexperienced knows what would happen.

With the operation of practically all kinds of plants, factories, mills, etc., so utterly dependent on rod and sheet packings to allow proper operation, why use any but thoroughly reliable and well-known products?

DANIEL'S P. P. P. ROD PACKING

Probably the best known rod packing on the market. Unequalled for the packing against steam, water, air, ammonia, and other fluids.

Many practical tests by experienced engineers under various conditions have clearly demonstrated that P.P.P. is the most economical rod packing to use. Its long life is remarkable, its ability to create a saving in the fuel bill is well known.

"The Story of Some Friction Test"

is a booklet that should be in the hands of everyone who has **anything** to do with rod packing, whether buyer or user.

EBONITE SHEET PACKING

Used exclusively in many of the largest power houses, factories, and machine shops, for high pressures, super-heated steam, hot water, ammonia, oils and acids and all other kinds of joints requiring packing.

EBONITE will hold a vibrating joint absolutely tight, and where there is a varying expansion or contraction of the pipes EBONITE is especially desirable.

Premier Meighen Discusses National Issues in MACLEAN'S

The Rt. Hon. Arthur Meighen, Prime Minister of Canada, has written for January 1st MACLEAN'S a forceful exposition of his platform and policy.

HE discusses the bi-lingual issue, the tariff, reconstruction, the growing unrest and unemployment — but he avers that the tariff is the "one great issue of our domestic politics?

"Why is it the issue?" queries Mr. Meighen. "It is the issue, I think, because the enemies of the Government cannot oppose us on any other."

Regarding the tariff, the Premier tells readers of MACLEAN'S: "We do not propose going any higher *on any single line of articles.*"

"Is Mr. Crerar hedging?" the Premier inquires.

Of Mr. Mackenzie King he says: "He can be quoted on almost every conceivable side of the tariff issue."

Articles by Mr. W. L. Mackenzie King and Mr. T. A. Crerar will follow in succeeding issues.

"The Drama of Our Great Forests"

A BIG INSTALMENT IN JANUARY 1st MACLEAN'S

This stirring story by Arthur Heming is continued in January 1st MacLean's, chock-full of wood-lore, fascinating yarns of the luring, frozen North, and amazing tales of actual adventure. The life history of the Canadian beaver, our national animal, is unfolded in a manner that surpasses fiction, as fact so often does if truly told by a masterful writer—"the beavers"—those wonderful amphibious animals of the Northland that display more intelligence, perseverance, prudence and morality than many a highly civilized human being."

Other Big Features

"The Big Time Man."
By C. W. Stephens.
A romantic story of the unromantic business of making bottles.

"Money and Motion Pictures."
By John W. McKay.
A Canadian who filmed "The Miracle Man."

"The Diamond Pickers."
By Madge MacBeth.
The girl detective finds how diamonds disappear by extra-human agency.

"Folling the 'Free Trader'."
By Kathrene and Robert Pinkerton.
A Hudson's Bay story, where the Indian outwits his white foe.

"The City of Peril."
By Arthur Stringer.
A big slice of this serial of Bolshevistic peril.

"When Toronto Grew Up"
By Col. Geo. H. Ham.
Anecdote after anecdote of the past fifty years in Toronto.

"Margot and Peter Flower."
By Mrs. "Margot" Asquith.
The commencement and course of an amazing eight years' flirtation.

If what you need is not advertised, consult our Buyers' Directory and write advertisers listed under proper heading.

Beatty Bros., Limited, Fergus, Ontario, with branches throughout Canada in a recent issue of their weekly sales bulletin, "Facts," give a very clear idea of the value of Hardware and Metal to the Canadian trade. This is what "Facts" has to say:—

"Do You Read Hardware & Metal?"

"We do not often take space in FACTS to boost any particular paper, but we are making an exception in the case of Hardware and Metal.

"If we did not know that so many of our hardware salesmen subscribed to it, we should be tempted to republish in FACTS some of their recent articles on the price situation.

"Some ten or fifteen trade papers—as distinct from farm papers—come into the FACTS editorial sanctum. There is none with half the weight and breadth of information that is possessed by Hardware and Metal.

"During the easier days of the past few months,—when the main question was not what the Sales Force could sell but what the Factory could supply—we may have been tempted to let Hardware and Metal go by the board.

"You can't afford to neglect it in these days. It is just full of authoritative information on the price situation in particular and hardware merchandising in general.

"So read it carefully. It gives you just the dope you need. When you tell the merchant that prices are not going to slump—well, he may not quite believe you. He feels you may have some axe to grind.

"But when you can quote or indicate some article in Hardware and Metal to prove your point,—it convinces.

"Remember, Hardware and Metal carries a lot of weight. It is known to be thoroughly unprejudiced and reliable. There are very few stronger trade papers in America so far as their own particular fields are concerned.

"So don't neglect your weekly reading of Hardware and Metal. Clip out any specially good points and paste them in your notebook for easy reference.

"The first two or three items on page 40 of the October 23 issue are dandies—probably you noticed them. If not, turn up your copy and read them.

"We all have to be well posted in these days or we go under. This is no time for the half-informed salesman to be on the road."

Rotary Continuous Heat-Treating Furnaces Used in Quantity Production of Pressed Steel Parts.

METALLURGISTS

The following advantages are secured by the Continuous Method of Heat-Treatment:

Bringing material up gradually to the final temperature.
Utilizing heat in spent gases to preheat material.
Exposing each piece to heat in same manner, to same temperature, for same length of time.
Uniformity not only of the individual piece but of the sections thereof as compared with the corresponding sections of other pieces.

DO THESE ADVANTAGES APPEAL TO YOU?

Write for Bulletin 217-T and learn whether the continuous method is adaptable to your product and manufacturing conditions.

It's human nature to be proud of work well done. We're justly proud of every bar of Lionroyal

Lionroyal

a royal lining for your bearings

Longer Wear per Bearing

That's what you want—isn't it? The smooth unity of hard and tough metals in Lionroyal insures longer wear. There are no hard spots to score your shafting. A perfect oil film is assured, and with proper lubrication the lining will wear indefinitely.

Even if you were to neglect or otherwise temporarily overlook lubrication, the result would not be serious, for Lionroyal is practically self-lubricating. You'll agree that's an important point.

You can feel implicit confidence in Lionroyal for all-around service. The accuracy and thoroughness of manufacture are made certain by the Stanley process of alloying.

BRITISH SMELTING & REFINING COMPANY LIMITED

Do You Know "Barnes-Made" Springs

Just inquire around among the various industries where springs are used:

Ask about—"Barnes-Made" Quality.

—Barnes' Deliveries.

—Barnes' methods of testing for Accuracy.

—Barnes' raw material—the Steel that we make ourselves for "Barnes-Made" products and for other manufacturers, too.

—Why "Barnes-Made" Springs reduce replacements to a minimum.

—Why "Barnes-Made" means *made right,* in exact conformity with specifications or requirements, reducing assembling costs to a minimum.

—Etc., etc., etc., etc.

Just hail a brother P. A. and put him through the third degree. He'll tell you that Barnes' Spring Service is based upon three generations' experience in manufacturing and designing springs — and that it MERITS YOUR CONFIDENCE!

Springs of steel, brass, phosphor bronze or vanadium—flat, coiled, spiral — compression, extension or torsion. Wire forming, spring washers, small parts of steel, brass, etc., in any finish. Assemblies. High Carbon Cold-Rolled Steel.

Booklet No. 9 shows a lot of springs you may need. How shall we address it?

It Pays To Keep Posted!

If you are not a subscriber to Canadian Machinery it will pay you to become one.

If you are a regular reader, you'll appreciate the value of the information to be secured. Pass the good word along to your friends.

Canadian Machinery is Canada's oldest exclusive machinery, iron and steel, and general metal-working industries paper. It is well established, well edited, well connected.

A careful study of its pages each week will serve to keep you posted on all that's new and worth knowing in machine shop circles.

Order now and ask for our Latest Export Number.

Free Tool Grinding Chart

Grind your cutting tools in exactly the right way to get best results—and you save time. That's obvious. It is precisely that that this Tool Grinding Chart enables you to do.

It has been adopted as standard by many firms that found it a long way better than guess work.

CANADIAN MACHINERY would like to see this Chart in every shop in the Dominion. Mail the coupon below for your copy to-day.

Shows at a glance Correct Clearance and Rake Angles for Cutting Tools

CANADIAN MACHINERY,

HENDEY

Gives Speed on Production Work, Too

Assign a piece-work operator to a Hendey Lathe and he knows—or will know very quickly—that he has secured the utmost in turning equipment to assist him in making big money.

This five-year-old Hendey is giving speed to production in the plant of the Dean Forging Company. It is shown facing the large bearing on a chrome nickel steel cam shaft forging. It is 7/16″ from the edge of the first cam to this face, from 1/16″ to 3/8″ of stock is removed. Production is 400 in 15 hours.

The speedy accuracy of Hendey Lathes, Shapers and Millers has increased production in hundreds of shops throughout Canada and the United States. Remember this when in need of additional machines yourself.

THE HENDEY MACHINE COMPANY
TORRINGTON, CONN., U.S.A.
